ABSTRACT

An assessment of emerging C-H activation catalysts of the type [(COD)Ir(IMes)(PR$_3$)]PF$_6$ in the deuteration of N-heterocycles is divulged. Substrate scope, competition experiments, and labelling of drug type molecules have revealed PR$_3$ = PPh$_3$ provides a broadly more applicable and widely effective catalyst system compared to other available complexes in the present series.

1. Introduction

The synthesis and supply of isotopically-labelled molecules has a sustained importance in the study of preparative chemistry, reaction mechanisms, and metabolic processes, with documented uses spanning a range of physical organic, organometallic, and pharmaceutical chemical sciences.$^1$ In one particularly active branch of such research, hydrogen isotope exchange (HIE) is commonly employed to deliver deuterium (D) or radioactive tritium (T) to pharmaceutical drug candidates in one synthetic step.$^2$ As well as circumventing the requirement for isotopically-enriched starting materials in synthesising tritiated drug candidates,$^{2c}$ HIE can also provide deuterated analogues for use as internal standards for mass spectrometry,$^3$ for kinetic isotope studies,$^1$ and for the alteration of reaction pathways in total syntheses.$^4$

Recently, one of our laboratories has focused on the development and understanding of ortho-directed HIE C-H activation processes using homogeneous iridium(I) complexes of the type 1 (Fig. 1).$^5$ Owing to the steric bulk and electron-donating power of the NHC/phosphine combination, these complexes have been shown to be significantly more active in the direct introduction of both D and T$^{2c}$ and produce less radioactive waste$^{2c}$ than in triraditions with commonly-used Crabtree’s catalyst, [(COD)Ir(PCy$_3$)(py)]PF$_6$. $^5$

Fig. 1. HIE catalysts bearing an NHC-phosphine ligand sphere.

Although we have shown these catalysts to be compatible with a range of directing groups routinely present in drug-like compounds, the focus has been mainly on ketones, amides, and nitro compounds.$^{2c}$ To date, we have explored comparatively few N-heterocyclic directing groups,$^{5c}$ despite the prevalence of such moieties in drug candidates. In this contribution, we explore the compatibility of complexes 1a-c with an appreciably enhanced array of N-heterocyclic directing groups for the ortho-deuteration of pharmaceutically-relevant aromatic compounds.

we conducted a series of competition experiments, employing heterocycles employed within this programme. To achieve this, Substrate (0.086 mmol), [Ir] (0.0043 mmol, 5 mol%), DCM (1 mL), D 

Fig. 2 Deuteriation of phenyl N-heterocycles with catalysts 1a–c. Conditions: Substrate (0.086 mmol), [Ir] (0.0043 mmol, 5 mol%), DCM (1 mL), D₂ (1 atm), 25 ºC, 1 h. Deuterium incorporation measured by 'H NMR and LC-MS (see ESI for details). The results shown are an average of two independent reaction runs.

2. Results and Discussion

Our studies began with the application of heteroaryl functionalised benzene derivatives, 6–11, with complexes 1a–c under the mild reaction conditions developed for use with these catalyst systems (Figure 2). We were encouraged to find that, in all cases, at least one catalyst from 1a–c was able to install >80% D in the phenyl ring adjacent to the N-heterocyclic directing group. Importantly, all isotopically labelled products were recovered in excellent yields. In the pyrimidine, 6, catalyst 1a was able to deliver excellent 93% deuteration to the expected ortho-positions, with this Ir species being found to be significantly more efficient than catalysts 1b and 1c. For imidazole 7, oxazole 8, oxazoline 9, isoxazole 10, and thiazole 11, all three catalysts delivered moderate to excellent levels of deuteration incorporation. Again, catalyst 1a was found to be the most efficient, except in the case of isoxazole 10, where complex 1b was most productive.

To further expand the substrates compatible with catalysts 1a–c for effective HIE, we studied the deuteriation of benzannulated compounds, 12–15 (Figure 3). For benzimidazole, 12, no deuterium incorporation was detected in the absence of a phenyl substituent. However, the 2-phenyl-substituted benzimidazole, 13, -benzoxazole, 14, and -benzothiazole, 15, were all deuterated with good to excellent levels of incorporation using one of catalysts 1a–c. Once again, it was clear that 1a (containing the comparatively least electron-rich phosphine ligand, PPh₃) was the most efficient and most generally applicable Ir catalyst. It should also be noted that, across the new substrates deuterated, catalyst series 1a–c was shown to be more active than Crabtree’s catalyst, 5, in eight of nine examples (see Experimental and ESI for details). In line with our previous studies, this serves to show that the NHC/phosphine ligand sphere on these iridium(I) catalysts is more generally effective in such homogeneous HIE processes when compared to the pyridine/phosphine ligand sphere of classical catalyst, 5.

Regio- and chemoselectivity is of fundamental and practical importance to the broadest range of C-H activation processes. As such, the penultimate part of our study aimed to rank the relative electronic directing group capabilities of the N-heterocycles employed within this programme. To achieve this, we conducted a series of competition experiments, employing two substrates in one reaction vessel, along with the most generally active catalyst, 1a. Applying this methodology to simple N-heterocycles 6–11, we have estimated the relative directing group strength to be in the order: 7 > 9 ~ 11 > 6 > 8 > 10 (Table 1) using a simple scoring system. This order is approximately proportional to the relative base strength of each substrate as determined by their pKₐ values. However, the predicted order based on the collective was inconsistent with individual competition experiments, showing that each case of directing group competition must be treated separately rather than as part of an ensemble.

![Tetrahedron](image-url)
We then expanded this study to investigate the directing group ability of benzannulated substrates. 13–15 (Table 2, rows 1-2). In competition experiments between each benzannulated substrate (13 vs. 14, 13 vs. 15, and 14 vs. 15), almost equal deuterium incorporation was found in every case, suggesting closely comparable coordinating abilities or rapid substrate exchange at iridium in these cases. Interestingly, comparing the benzannulated substrates against their simpler analogues (7 vs. 13, 8 vs. 14, and 11 vs. 15; Table 2, rows 3-5), closely equivalent deuterium incorporation was, again, observed in all cases. This infers that the increased size of the benzannulated substrates imparts only minimal steric encumbrance.

In the final part of our study, we aimed to apply this emerging N-heterocyclic directing group advantage and understanding to the deuterium labelling of multifunctional, drug-like molecules from our available inventory. Accordingly, we investigated the labelling of oxazoles 16 and 17, and thiazole 18, using the optimal catalyst, 1a (Table 3). For the related oxazoles 16 and 17, good levels of both D-incorporation (in the expected positions) and isolated yields were achieved under the standard conditions in DCM (Entries 1 and 4). However, having previously shown that catalysts such as 1a operate across a wider solvent range,7b,7d we were able to improve on this initial success, finding that comparable or even higher levels of D-incorporation were possible in MeOH (Entries 2 and 5) and THF (Entries 3 and 6), albeit at slightly elevated temperatures in the latter solvent. Turning to thiazole derivative 18 (Entries 7–9), we were intrigued to observe no deuterium incorporation on the trifluoromethylated ring adjacent to the thiazole (position 1). Instead, labelling was observed solely adjacent to the alternative, oxadiazolone N-heterocycle in the molecule (position 2). This heterocycle is considered to be similar (but not identical) to imidazole due to the shared amide-based directing group moiety. This labelling outcome is contrary to what may have been predicted on the basis of the single competition experiment using an imidazole and a thiazole (see Table 3, 7 vs. 11), but is in line with what would be predicted on the basis of the series of competition experiments from Table 1 overall (see determined general directing group order, vide supra). To show that competitive binding was directly influencing the labelling of substrate 18, we re-ran the reaction from Table 3, Entry 9 using 25, 50, and 100 mol% 1a. Under these conditions (and by LC-MS analysis), the molecule was increasingly deuterated across the three possible labelling sites instead of at just one site (see ESI for details). This suggests that, at higher catalyst loadings, the less favoured directing group has an enhanced possibility to coordinate the iridium catalyst. More broadly, these outcomes serve to reinforce our conclusions based on earlier computational studies.7a Specifically, directing group chemoselectivity in multifunctional molecules in labelling with catalysts like 1a cannot be predicted on the basis of a sole competition experiment employing individual monofunctionalised molecules containing the various directing groups present in the single, multifunctional molecule.7a,11 This is particularly important when applying commonly low catalyst loadings of approximately 5 mol%.

3. Conclusion

In summary, we have shown that hydrogen isotope exchange catalysts 1a–c are compatible with an expanded array of pharmaceutically-relevant N-heterocyclic directing groups, namely pyrimidine, imidazole, oxazole, oxazoline, isoxazole, thiazole, benzimidazole, benzoxazole, and benzothiazole. Deuterium labelling of molecules containing these directing groups was achieved with high levels of incorporation and
excellent isolated yields, employing at least one of the commercialised catalysts 1a-e. From these studies, catalyst 1a has proven to be the most versatile and most broadly applicable. Employing this catalyst, competition studies between simple phenyl N-heterocycles revealed that directing group selectivity has to be considered on a case by case basis and cannot be predicted using a scoring system for the ensemble of competition experiments. This is especially important when considering multifunctional, drug-like compounds, as was demonstrated in the labelling of compound 18. Similar competition experiments employing benzannulated heterocycles revealed these species to compete equally with their parent heterocycle in reaction with the catalyst, such that: imidazole ~ benzimidazole; oxazole ~ benzoazole; and thiazole ~ benzothiazole. As part of our future work, we are expanding this fundamental analysis of chemoselectivity to the deuterium and tritium labelling of a broader series of multifunctional drug compounds.

4. Experimental section

4.1. General information

All substrates, catalysts, and solvents were obtained from commercial suppliers and used without further purification. All labelling reactions were carried out on a Heidolph Synthesis 1 Liquid 16 device. Flash column chromatography was carried out using Merck kieselgel 60 silica gel (particle size: 63-200). Liquid 16 device. Flash column chromatography was carried out using Merck kieselgel 60 silica gel (particle size: 63-200). Liquid 16 device. Flash column chromatography was carried out using Merck kieselgel 60 silica gel (particle size: 63-200).

4.2. General Procedures

4.2.1. General Procedure A for Hydrogen Isotope Exchange with Simple Substrates 6 - 15

The water inlet for the carousel reflux system was turned on prior to any further reaction set up. To a carousel tube was added the substrate of choice (0.086 mmol, unless otherwise stated) and iridium(I) catalyst (0.0043 mmol, 5 mol%, unless otherwise stated) under air. The desired solvent (1 mL) was added, rinsing the inner walls of the tube. The tube was then sealed at the screw cap (with gas inlet left open) under air before initiating the carousel shaking motion (720 rpm) and setting the reaction temperature (25 or 50 °C). The flask was twice evacuated and flushed with deuterium via a balloon. The carousel tube gas inlet was then closed, creating a sealed atmosphere of deuterium. After sealing the flask, the reaction timer was started, and a quick red to clear/yellow colour change was observed. The reaction mixture was stirred for 1 h before removing excess deuterium and replacing with air. The yellow solution was then washed with DCM and transferred to a single necked flask before removing the solvent under reduced pressure. The residue was filtered through a short plug of silica, eluting with ethyl acetate (2 x 3 mL), and 2% MeOH where necessary, depending on the substrate of choice. An LC-MS sample (~2 μL) was taken directly from the combined filtered fractions. The solvent was evacuated again and the residue analysed directly by 1H NMR spectroscopy. The level and regioselectivity of deuterium incorporation in the substrate was determined by 1H NMR spectroscopy (for detail, see the ESI). Yields and %D incorporation are the averages of two reaction runs.

4.2.2. General Procedure C for Hydrogen Isotope Exchange with Pharmaceuticals 16-18 with Catalyst 1a

Following General Procedure A, each substrate was employed using 22 μmol in conjunction with 1.1 μmol of catalyst 1a (1.1 mg, 5 mol%) and 1 mL solvent

4.3. Hydrogen Isotope Exchange Experiments

4.3.1. Hydrogen Isotope Exchange with Simple Substrates 6 – 15

2-Phenylpyrimidine 6

Following General Procedure A, exchange of 2-phenylpyrimidine (13.4 mg) in the presence of catalyst 1a (4.4 mg) gave [2',6'-1H]-6 (12.8 mg, 96%, 93%D).

Following General Procedure A, exchange of 2-phenylpyrimidine (13.4 mg) in the presence of catalyst 1b (4.6 mg) gave [2',6'-2H]-6 (12.4 mg, 93%, 42%D).

Following General Procedure A, exchange of 2-phenylpyrimidine (13.4 mg) in the presence of catalyst 1c (3.8 mg) gave [2',6'-3H]-6 (12.8 mg, 96%, 14%D).

Following General Procedure A, exchange of 2-phenylpyrimidine (13.4 mg) in the presence of catalyst 5 (3.4 mg) gave [2',6'-1H]-6 (11.6 mg, 86%, 28%D).

Incorporation expected at δ 8.44-8.41.

Incorporation determined against δ 7.17.

2-Phenylimidazole 7

Following General Procedure A, exchange of 2-phenylimidazole (12.4 mg) in the presence of catalyst 1a (4.4 mg) gave [2',6'-2H]-7 (11.7 mg, 94%, 89%D).

Following General Procedure A, exchange of 2-phenylimidazole (12.4 mg) in the presence of catalyst 1b (4.6 mg) gave [2',6'-3H]-7 (11.2 mg, 91%, 73%D).

Following General Procedure A, exchange of 2-phenylimidazole (12.0 mg) in the presence of catalyst 1c (3.8 mg) gave [2',6'-3H]-7 (12.8 mg, 95%, 70%D).

Following General Procedure A, exchange of 2-phenylimidazole (12.4 mg) in the presence of catalyst 5 (3.4 mg) gave [2',6'-2H]-7 (12.2 mg, 98%, 76%D).

Incorporation expected at δ 7.94-7.92.

Incorporation determined against δ 7.32.

2-Phenylloxazole 8

Following General Procedure A, exchange of 2-phenylloxazole (12.4 mg) in the presence of catalyst 1a (4.4 mg) gave [2',6'-2H]-8 (10.0 mg, 80%, 92%D).
Following General Procedure A, exchange of 2-phenyloxazole 8 (12.4 mg) in the presence of catalyst 1b (4.6 mg) gave [2',6',5'-\text{H}_3]-8 (9.8 mg, 79%, 79%D).

Following General Procedure A, exchange of 2-phenyloxazole 8 (12.0 mg) in the presence of catalyst 1e (3.8 mg) gave [2',6',5'-\text{H}_3]-8 (8.6 mg, 70%, 91%D).

Following General Procedure A, exchange of 2-phenyloxazole 8 (12.4 mg) in the presence of catalyst 5 (3.4 mg) gave [2',6',5'-\text{H}_3]-8 (6.4 mg, 52%, 87%D).

$\delta_\text{H}$ (300 MHz, MeOD-d$_4$) 8.03-7.97 (m and overlapping s, 3H), 7.54-7.48 (m, 3H, 7.29 (s, 1H).

Incorporation determined against $\delta$ 8.03-7.97.

Incorporation determined against $\delta$ 7.50-7.48.

2-Phenyloxazoline 9

Following General Procedure A, exchange of 2-phenyloxazoline 9 (12.6 mg) in the presence of catalyst 1a (4.4 mg) gave [2',6',5'-\text{H}_3]-9 (12.4 mg, 99%, 83%D).

Following General Procedure A, exchange of 2-phenyloxazoline 9 (12.6 mg) in the presence of catalyst 1b (4.6 mg) gave [2',6',5'-\text{H}_3]-9 (11.8 mg, 94%, 75%D).

Following General Procedure A, exchange of 2-phenyloxazoline 9 (12.6 mg) in the presence of catalyst 1c (3.8 mg) gave [2',6',5'-\text{H}_3]-9 (11.8 mg, 94%, 80%D).

Following General Procedure A, exchange of 2-phenyloxazoline 9 (12.6 mg) in the presence of catalyst 5 (3.4 mg) gave [2',6',5'-\text{H}_3]-9 (2.8 mg, 23%, 76%D).

$\delta_\text{H}$ (300 MHz, CDCl$_3$) 7.95-7.92 (m, 2H), 7.49-7.24 (m, 3H), 4.37 (t, 2H, $J = 9.6$ Hz), 4.00 (t, 2H, $J = 9.6$ Hz).

Incorporation determined against $\delta$ 7.95-7.92.

Incorporation determined against $\delta$ 4.37.

5-Phenylisoxazole 10

Following General Procedure A, exchange of 5-phenylisoxazole 10 (12.4 mg) in the presence of catalyst 1a (4.4 mg) gave [2',6',5'-\text{H}_3]-10 (11.6 mg, 93%, 86%D).

Following General Procedure A, exchange of 5-phenylisoxazole 10 (12.4 mg) in the presence of catalyst 1b (4.6 mg) gave [2',6',5'-\text{H}_3]-10 (12.4 mg, 100%, 95%D).

Following General Procedure A, exchange of 5-phenylisoxazole 10 (12.4 mg) in the presence of catalyst 1c (3.8 mg) gave [2',6',5'-\text{H}_3]-10 (12.0 mg, 95%, 89%D).

Following General Procedure A, exchange of 5-phenylisoxazole 10 (12.4 mg) in the presence of catalyst 5 (3.4 mg) gave [2',6',5'-\text{H}_3]-10 (9.0 mg, 73%, 54%D).

$\delta_\text{H}$ (300 MHz, DMSO-d$_6$) 9.01 (d, 1H, $J = 1.7$ Hz), 7.91-7.88 (m, 2H), 7.56-7.50 (m, 3H), 7.16 (d, 1H, $J = 1.7$ Hz).

Incorporation determined at $\delta$ 7.91-7.88.

Incorporation determined against $\delta$ 7.16.

2-Phenylthiazole 11

Following General Procedure A, exchange of 2-phenylthiazole 11 (13.8 mg) in the presence of catalyst 1a (4.4 mg) gave [2',6',5'-\text{H}_3]-11 (12.2 mg, 89%, 82%D).

Following General Procedure A, exchange of 2-phenylthiazole 11 (13.8 mg) in the presence of catalyst 1b (4.6 mg) gave [2',6',5'-\text{H}_3]-11 (11.0 mg, 80%, 44%D).

Following General Procedure A, exchange of 2-phenylthiazole 11 (13.8 mg) in the presence of catalyst 1e (3.8 mg) gave [2',6',5'-\text{H}_3]-11 (13.6 mg, 98%, 72%D).

Following General Procedure A, exchange of 2-phenylthiazole 11 (13.8 mg) in the presence of catalyst 5 (3.4 mg) gave [2',6',5'-\text{H}_3]-11 (10.8 mg, 78%, 59%D).

$\delta_\text{H}$ (300 MHz, DMSO-d$_6$) 7.97-7.93 (m, 3H), 7.78 (d, 1H, $J = 3.3$ Hz), 7.54-7.48 (m, 3H).

Incorporation determined at $\delta$ 7.97-7.93.

Incorporation determined against $\delta$ 7.54-7.48.

Benzimidazole 12

Following General Procedure A, exchange of benzimidazole 12 (10.2 mg) in the presence of catalyst 1a (4.4 mg) gave benzimidazole 12 (10.0 mg, 99%, 0%D).

Following General Procedure A, exchange of benzimidazole 12 (10.2 mg) in the presence of catalyst 1b (4.6 mg) gave benzimidazole 12 (10.0 mg, 99%, 0%D).

Following General Procedure A, exchange of benzimidazole 12 (10.2 mg) in the presence of catalyst 1c (3.8 mg) gave benzimidazole 12 (10.0 mg, 99%, 0%D).

Following General Procedure A, exchange of benzimidazole 12 (10.2 mg) in the presence of catalyst 5 (3.4 mg) gave benzimidazole 12 (10.0 mg, 99%, 0%D).

$\delta_\text{H}$ (300 MHz, DMSO-d$_6$) 8.15 (s, 1H, H$_3$), 7.62-7.59 (m, 2H, H$_2$), 7.29-7.23 (m, 2H, H$_2$).

No incorporation expected.

2-Phenylbenzimidazole 13

Following General Procedure A, exchange of 2-phenylbenzimidazole 13 (16.8 mg) in the presence of catalyst 1a (4.4 mg) gave [2',6',5'-\text{H}_3]-13 (14.8 mg, 88%, 84%D).

Following General Procedure A, exchange of 2-phenylbenzimidazole 13 (16.8 mg) in the presence of catalyst 1b (4.6 mg) gave [2',6',5'-\text{H}_3]-13 (14.9 mg, 89%, 83%D).

Following General Procedure A, exchange of 2-phenylbenzimidazole 13 (16.8 mg) in the presence of catalyst 1c (3.8 mg) gave [2',6',5'-\text{H}_3]-13 (13.8 mg, 82%, 72%D).

Following General Procedure A, exchange of 2-phenylbenzimidazole 13 (16.8 mg) in the presence of catalyst 5 (3.4 mg) gave [2',6',5'-\text{H}_3]-13 (15.3 mg, 91%, 72%D).

$\delta_\text{H}$ (300 MHz, DMSO-d$_6$) 12.90 (s, 1H), 8.19-8.17 (m, 2H), 7.60-7.47 (m, 5H), 7.23-7.18 (m, 2H).

Incorporation determined at $\delta$ 8.19-8.17.

Incorporation determined against $\delta$ 7.23-7.18.
2-Phenylbenzoxazole 14

Following General Procedure A, exchange of 2-phenylbenzoxazole 14 (16.8 mg) in the presence of catalyst \( \text{Ia} \) (4.4 mg) gave \( [2',6'-\text{H}_2]-14 \) (15.2 mg, 94%, 90%)D.

Following General Procedure A, exchange of 2-phenylbenzoxazole 14 (16.8 mg) in the presence of catalyst \( \text{Ib} \) (4.6 mg) gave \( [2',6'-\text{H}_2]-14 \) (16.2 mg, 96%, 82%)D.

Following General Procedure A, exchange of 2-phenylbenzoxazole 14 (16.8 mg) in the presence of catalyst \( \text{Ic} \) (3.8 mg) gave \( [2',6'-\text{H}_2]-14 \) (16.0 mg, 95%, 80%)D.

Following General Procedure A, exchange of 2-phenylbenzoxazole 14 (16.8 mg) in the presence of catalyst \( \text{Id} \) (3.4 mg) gave \( [2',6'-\text{H}_2]-14 \) (16.2 mg, 96%, 96%)D.

\( \delta_0 \) (300 MHz, MeOD-d\(_4\)) 8.23-8.20 (m, 2H), 7.73-7.70 (m, 1H), 7.67-7.64 (m, 1H), 7.59-7.53 (m, 3H), 7.43-7.36 (m, 2H).

Incorporation expected at \( \delta \) 8.23-8.20.

Incorporation determined against \( \delta \) 7.43-7.36.

2-Phenylbenzothiazole 15

Following General Procedure A, exchange of 2-phenylbenzothiazole 15 (18.2 mg) in the presence of catalyst \( \text{Ia} \) (4.4 mg) gave \( [2',6'-\text{H}_2]-15 \) (18.0 mg, 99%, 94%)D.

Following General Procedure A, exchange of 2-phenylbenzothiazole 15 (18.2 mg) in the presence of catalyst \( \text{Ib} \) (4.6 mg) gave \( [2',6'-\text{H}_2]-15 \) (17.0 mg, 93%, 60%)D.

Following General Procedure A, exchange of 2-phenylbenzothiazole 15 (18.2 mg) in the presence of catalyst \( \text{Ic} \) (3.8 mg) gave \( [2',6'-\text{H}_2]-15 \) (17.2 mg, 95%, 31%)D.

Following General Procedure A, exchange of 2-phenylbenzothiazole 15 (18.2 mg) in the presence of catalyst \( \text{Id} \) (3.4 mg) gave \( [2',6'-\text{H}_2]-15 \) (17.2 mg, 95%, 81%)D.

\( \delta_0 \) (300 MHz, CDCl\(_3\)) 8.10-8.05 (m, 3H), 7.90 (d, 1H, \( J = 9.0 \) Hz), 7.50-7.46 (m, 4H), 7.40-7.35 (m, 1H).

Incorporation expected at \( \delta \) 8.10-8.05.

Incorporation determined against \( \delta \) 7.40-7.35.

4.3.2. Hydrogen Isotope Exchange of Drug-like Heterocycles 16-18 with Catalyst 1a

Oxazole 16

Following General Procedure C, exchange of pharmaceutical 16 (8.4 mg) in the presence of catalyst \( \text{Ia} \) (1.1 mg) in DCM (1 mL) at 25 °C gave \( [\text{H}]_{-16} \) (8.0 mg, 95%, 83%)D; see Table 3 for position of D incorporation.

Following General Procedure C, exchange of pharmaceutical 16 (8.4 mg) in the presence of catalyst \( \text{Ia} \) (1.1 mg) in MeOH (1 mL) at 25 °C gave \( [\text{H}]_{-16} \) (7.9 mg, 94%, 80%)D; see Table 3 for position of D incorporation.

Following General Procedure C, exchange of pharmaceutical 16 (8.4 mg) in the presence of catalyst \( \text{Ia} \) (1.1 mg) in THF (1 mL) at 50 °C gave \( [\text{H}]_{-16} \) (6.1 mg, 73%, 95%)D; see Table 3 for position of D incorporation.

\( \delta_0 \) (300 MHz, DMSO-d\(_6\)) 13.08 (s, 1H), 8.13 (s, 1H), 7.99-7.95 (m, 2H), 7.54-7.52 (m, 3H), 7.29-7.16 (m, 3H), 4.47 (s, 2H), 4.40 (s, 2H), 3.54 (t, 2H, \( J = 6.5 \) Hz), 3.45 (t, 2H, \( J = 6.5 \) Hz), 2.29 (s, 3H), 1.78 (quintet, 2H, \( J = 6.5 \) Hz).

Incorporation expected at \( \delta \) 7.99-7.95.

Incorporation determined against \( \delta \) 2.29.

Oxazole 17

Following General Procedure C, exchange of pharmaceutical 17 (9.9 mg) in the presence of catalyst \( \text{Ia} \) (1.1 mg) in DCM (1 mL) at 25 °C gave \( [\text{H}]_{-17} \) (8.9 mg, 90%, 82%)D; see Table 3 for position of D incorporation.

Following General Procedure C, exchange of pharmaceutical 17 (9.9 mg) in the presence of catalyst \( \text{Ia} \) (1.1 mg) in MeOH (1 mL) at 25 °C gave \( [\text{H}]_{-17} \) (8.9 mg, 90%, 85%)D; see Table 3 for position of D incorporation.

Following General Procedure C, exchange of pharmaceutical 17 (9.9 mg) in the presence of catalyst \( \text{Ia} \) (1.1 mg) in THF (1 mL) at 50 °C gave \( [\text{H}]_{-17} \) (9.2 mg, 93%, 95%)D; see Table 3 for position of D incorporation.

\( \delta_0 \) (300 MHz, DMSO-d\(_6\)) 13.06 (s, 1H), 7.81 (d, 2H, \( J = 8.2 \) Hz), 7.33-7.16 (m, 5H), 4.53 (s, 2H), 4.39 (s, 2H), 2.37-2.36 (overlapping singlets, 6H), 2.29 (s, 3H).

Incorporation expected at \( \delta \) 7.81.

Incorporation determined against \( \delta \) 2.29.

Thiazole-oxadiazolone 18

Following General Procedure C, exchange of pharmaceutical 18 (10.2 mg) in the presence of catalyst \( \text{Ia} \) (1.1 mg) in DCM (1 mL) at 25 °C returned 18 (7.7 mg, 75%, 0%)D.

Following General Procedure C, exchange of pharmaceutical 18 (10.2 mg) in the presence of catalyst \( \text{Ia} \) (1.1 mg) in MeOH (1 mL) at 25 °C gave \( [\text{H}]_{-18} \) (7.9 mg, 77%, 66%)D; see Table 3 for position of D incorporation.

Following General Procedure C, exchange of pharmaceutical 18 (10.2 mg) in the presence of catalyst \( \text{Ia} \) (1.1 mg) in THF (1 mL) at 50 °C gave \( [\text{H}]_{-18} \) (9.3 mg, 91%, 82%)D; see Table 3 for position of D incorporation.

\( \delta_0 \) (300 MHz, DMSO-d\(_6\)) 12.79 (s, 1H), 8.13 (d, 2H, \( J = 8.1 \) Hz), 7.86 (d, 2H, \( J = 8.1 \) Hz), 7.67 (d, 1H, \( J = 8.7 \) Hz), 7.44 (d, 1H, \( J = 2.5 \) Hz), 7.23 (dd, 1H, \( J = 8.7 \) Hz, \( J = 2.5 \) Hz), 5.51 (s, 2H), 2.50 (s, ~3H, overlapping with residual DMSO).

Incorporation possible at \( \delta \) 7.67 (observed as detailed by that shown in Table 3, Entries 7 – 9), and 8.13.

Incorporation determined against \( \delta \) 7.23.

Acknowledgments

We would like to thank the Carnegie Trust (M.R.) for funding.
