Mix and match: The carboxyamido moiety of tetracyclines is important for their bioactivity. Through rational biosynthetic
engineering, biosynthesis genes (OxyD, OxyP) from the oxytetracycline (OTC) polyketide synthase (PKS) from Streptomyces rimosus were expressed in Amycolatopsis sulphurea, a producer of the atypical tetracycline chelocardin (CHD). The resulting CHD analogue (CDCHD) was produced at high yield and exhibits greatly improved antibacterial activity.

Combinatorial Biosynthesis

antibiotics
biosynthesis
chelocardin
polyketides
tetracyclines

Antimicrobial resistance and the shortage of novel antibiotics have led to an urgent need for new antibacterial drug leads. Several existing natural product scaffolds (including chelocardins) have not been developed because their suboptimal pharmacological properties could not be addressed at the time. It is demonstrated here that reviving such compounds through the application of biosynthetic engineering can deliver novel drug candidates. Through a rational approach, the carboxyamido moiety of tetracyclines (an important structural feature for their bioactivity) was introduced into the chelocardins, which are atypical tetracyclines with an unknown mode of action. A broad-spectrum antibiotic lead was generated with significantly improved activity, including against all Gram-negative pathogens of the ESKAPE panel. Since the lead structure is also amenable to further chemical modification, it is a platform for further development through medicinal chemistry and genetic engineering.

The evolution of multidrug-resistant pathogens presents one of the greatest challenges to modern health care. There is a critical shortage of effective antibiotics, particularly against Gram-negative pathogens belonging to the ESKAPE group.
(see Table\(^1\)), including *Pseudomonas aeruginosa*, which is an important pathogen that causes hospital-acquired infections.\(^1\) Consequently, new antibiotics from novel antibiotic classes that bypass current resistance mechanisms, and preferably with a new mode of action,\(^2\) need to be translated rapidly into the clinic. Approaches such as screening natural product libraries and developing chemically synthesised antibiotics based on novel targets have shown that the identification of promising anti-infective lead structures is a rare event.\(^3\)

Based on more than 70\(^\text{+}^\) years of antibacterial drug development, an attractive alternative is to reassess unexploited and underutilised structural scaffolds of proven antibacterial potency and resistance-breaking properties, and to develop these further by using cutting-edge synthetic biology.

Antibiotics such as tetracyclines (TCs), which were formerly highly-effective against both Gram-positive and Gram-negative pathogens, are now ineffective owing to widespread antibiotic resistance.\(^4\) TCs are bacteriostatic; the first major class of therapeutics to be termed broad-spectrum antibiotic.\(^5\) Clinically-important TCs, such as doxycycline, minocycline, and glycylcyclines (a new class of TCs), are termed typical TCs. Their mode of action involves binding to the ribosome during polypeptide elongation to inhibit translation.\(^6\) Chelocardin (CHD, \(^3\); Figure\(^1\)), which is produced by *Amycolatopsis sulphurea*,\(^7\) is regarded as a structurally atypical TC and shows bactericidal activity.\(^8\) Initial data on the mode of action of CHD exist, but the exact mechanism of action has yet to be elucidated.\(^8,^9\) CHD is effective against many multidrug-resistant pathogens, including some difficult-to-treat Gram-negative bacteria. Importantly, it is also effective against TC-resistant strains, except for *Pseudomonas aeruginosa* (Table\(^1\)).\(^10\) No toxicity from CHD was observed
following oral administration in rats or dogs.\textsuperscript{[11]} In a small Phase \textsuperscript{II} clinical study in the late 1970s, twelve patients receiving CHD orally were cured of urinary-tract infections (pyelonephritis).\textsuperscript{[11]} Only one minor gastrointestinal adverse event was reported, while three patients were cleared of tetracycline-resistant infections, thus showing the potential of CHD to combat difficult infections. Nevertheless, CHD was not developed further as an antibiotic.

We re-examined CHD activity with a panel of multidrug-resistant clinical isolates (Table\textsuperscript{[1]}\textsuperscript{1}) and the results confirm its reported potency.\textsuperscript{[10]} Although CHD has the typical four-ring TC backbone, it also has several unique structural features that are believed to contribute to a mode of action most likely different to that of other TCs. Compared to clinically used TCs these features include: an alternative aromatization pattern at rings \textsuperscript{D} and \textsuperscript{C}; functionalization of CHD at \textsuperscript{9}; and opposite sterochemistry of the non-methylated amino group at \textsuperscript{4} (Figure\textsuperscript{[1]}\textsuperscript{1}).

Furthermore, whereas typical TCs bind to the ribosome in a cleft into which TCs fit owing to a kink between rings \textsuperscript{A} and \textsuperscript{B},\textsuperscript{[12]} CHD is a more planar molecule and consequently may not bind to the ribosome. No cross-resistance is known. One important feature of all medically-important TCs is the carboxyamido moiety at \textsuperscript{2} (1, Figure\textsuperscript{[1]}\textsuperscript{1}). In contrast, CHD carries an acetyl group at \textsuperscript{2} (3, Figure\textsuperscript{[1]}\textsuperscript{1}). Biosynthetically, this difference is due to priming by acetate instead of malonate during initiation (Figure\textsuperscript{[2]}\textsuperscript{[1]}\textsuperscript{2}).\textsuperscript{[13]} Although the exact mechanism of initiation in oxytetracycline (OTC) biosynthesis is still not well understood, it is carried out by a minimal polyketide synthase (PKS)\textsuperscript{[?]}\textsuperscript{[?]}\textsuperscript{[?]}\textsuperscript{[?]}\textsuperscript{[?]}\textsuperscript{[?]}\textsuperscript{[?]}.\textsuperscript{[?]}\textsuperscript{[?]}\textsuperscript{[?]}\textsuperscript{[?]}\textsuperscript{[?]}\textsuperscript{[?]}\textsuperscript{[?] OxyABC, consisting of two ketosynthase units KS\textsubscript{a} and KS\textsubscript{b}, and an acyl-carrier protein (ACP), an amidotransferase (AMT) OxyD, which catalyzes the transamination reaction of malonate to malonamate (Figure\textsuperscript{[2]}\textsuperscript{[1]}\textsuperscript{2}), and an acyltransferases (AT) homologue,
OxyP. The function of the AT domain in OTC biosynthesis is not yet clearly defined. Interestingly, inactivation of oxyP did not abolish the biosynthesis of OTC but did increase the proportion of 2-acetyl-2-decarboxyamido-oxytetracycline (2, ADOTC) compared to OTC (1; Figure1). Moreover, the carboxyamido moiety in OTC is crucial for the antibacterial activity of typical TCs. Recently, we reported the cloning of the gene cluster for CHD biosynthesis, which enabled the production of CHD analogues by using biosynthetic engineering. Since CHD is exclusively acetate-primed (Figure2b), the CHD biosynthetic cluster, as expected, contained no AT or AMT homologue. We thus attempted to prime CHD biosynthesis with the carboxyamido moiety. Aiming to produce an amidated analogue of CHD, specifically 2-carboxyamido-2-deacetyl-chelocardin (CDCHD, 4; Figure1b), oxyD and oxyP from the S. rimosus otc gene cluster were introduced into A. sulphurea individually and in combination by using three integrative plasmids: pAB03oxyD, pAB03oxyP and pAB03oxyDP (FigureS1 in the Supporting Information). The resulting A. sulphurea transformants were analyzed for production of CHD and CDCHD by HPLC (FigureS2a) and LC--MS (FigureS3). Remarkably, in the genetically engineered PKS system of chd in A. sulphurea, efficient malonamate priming is indeed possible but, interestingly, it is dependent on both oxyP and oxyD. This is in contrast to OTC biosynthesis in S. rimosus, where oxyP is practically dispensable. Biosynthesis of the malonamate-primed CDCHD was efficient, reaching a yield of around 80% of the total CHD produced by this strain (FigureS2). The structure of CDCHD, particularly the presence of the carboxyamido moiety, was confirmed by LC--MS, HRMS, and 2D NMR spectroscopy (Figure3 for the most important NMR correlations, also see the Supporting information). Incomplete conversion of CHD into CDCHD could be due to insufficient supply/processing of the putative starter unit, malonamyl-CoA, or competition by acetate starter units through direct transfer to the KSα.
Engineered enzymes often produce the desired product at significantly lower yield, thus seriously hampering downstream development.[17] Remarkably, however, the highest yield of CDCHD in the recombinant strain containing pAB03oxyDP was around 400 mg L<sup>-1</sup> (Figure S2b), compared to a yield of 900 mg L<sup>-1</sup> CHD achieved when using the wild-type A. sulphurea strain containing an empty plasmid.

Next, we isolated CDCHD and undertook comparative in vitro testing of CHD and CDCHD against a collection of well-characterised multidrug-resistant clinical isolates (Table 1 and the Supporting Information). Remarkably, the in vitro activity of CDCHD against these isolates was usually 2--4 times higher than that of CHD, thus confirming the importance of the 2-carboxyamido moiety for activity. For multidrug-resistant enterobacteria, methicillin-resistant Staphylococcus aureus, and glycopeptide-resistant Enterococcus faecium, CDCHD showed in vitro activity superior to that of CHD, with corresponding MIC<sub>90</sub> and MIC<sub>50</sub> values differing 2- to 4-fold. CDCHD showed a remarkable improvement compared to CHD against Klebsiella pneumoniae, which was inhibited at 16 μg mL<sup>-1</sup> or less by CHD and gave MIC<sub>90</sub> and MIC<sub>50</sub> values for CDCHD below 4 μg mL<sup>-1</sup>. CHD was only slightly less active compared to CDCHD against A. baumannii and almost inactive against P. aeruginosa (for which the MIC<sub>90</sub> value was >64 μg mL<sup>-1</sup>; Table 1). Importantly, CDCHD showed much higher in vitro activity against P. aeruginosa compared to CHD: 13 out of 15 multidrug-resistant isolates were inhibited at 16 μg mL<sup>-1</sup> or lower. However, the MIC<sub>50</sub> (8 μg mL<sup>-1</sup>) and MIC<sub>90</sub> (32 μg mL<sup>-1</sup>) values for CDCHD against P. aeruginosa were still 8- to 16-times higher than with S. aureus or E. faecium (2--4 μg mL<sup>-1</sup>). Relatively high MIC values against A. baumannii and P. aeruginosa and some multidrug-resistant K. pneumoniae species may indicate the involvement of intrinsic resistance mechanisms (e.g., efflux pumps). Additional studies to define the mechanisms of
resistance to CHD and CDCHD are currently ongoing in our laboratories in order to understand the bacterial strategies used to escape their effects.

Although the enzymatic mechanisms leading to carboxyamido moiety formation in TCs is of medicinal interest,\[^{16,18}\] our study is, to the best of our knowledge, the first successful heterologous expression of the AT and AMT from the otc cluster to derive a novel malonamate-primed molecule. The addition of this carboxyamido moiety significantly increases the biological activity of CHD. The acetate-primed impurity of OTC, ADOTC (2), also shows a tenfold reduction in antibacterial activity.\[^{19}\] Our findings for CHD are thus in agreement with the structure--activity relationships (SAR) found in typical TC antibiotics.\[^{14}\]

Our current understanding of the priming reactions in type^^II PKSs, which mostly involve minimal PKS ketosynthase complexes\[^{13,20}\] and an additional auxiliary acyltransferase (AT), is still limited, particularly when considering applying combinatorial approaches to generate potentially useful compounds. Reconstitution of the OTC minimal PKS in a heterologous host resulted in the biosynthesis of a truncated polyketide initiated with acetate. The addition of oxyD alone to this artificial system was sufficient to produce the amidated derivative as the major product.\[^{16}\] Thus suggesting that rather than being an acyltransferase, OxyP is a thiolase that suppresses priming by acetate by removing the competing acetyl units, as similarly observed in other type^^II PKS systems.\[^{21}\] However, in contrast to the priming steps in OTC biosynthesis,\[^{13}\] where the AMT oxyD alone is sufficient for the efficient production of OTC, when only oxyD was expressed in A. sulphurea, amidated CDCHD was biosynthesised in very low yield (Figure^^S2). The involvement of OxyP thus has much greater importance in the priming of CDCHD.

Most of the semisynthetic TCs used in the clinic, or currently in clinical development, derive from 6-
demethyltetracyclines (6-DMTCs). New approaches for total synthesis routes were recently reported to further expand the chemical diversity of the TC scaffold. Powerful biosynthetic engineering routes for the development of TC analogues have also been reported. Our current report of the incorporation of the carboxyamido moiety into chelocardins provides a unique diversification of the TC backbone and the resulting derivative shows potent antibacterial activity and could prove to be a promising drug lead.

Overall we have demonstrated efficient incorporation of the carboxyamido starter moiety, which is known to be important for tetracycline activity, into CHD. A high yield of this novel compound (CDCHD) was obtained, and the process should be directly transferable to an industrial scale. Therefore, we not only demonstrated the utility of this biosynthetic engineering approach but also developed a unique tetracycline lead with potent antibacterial activity. This compound class can now be diversified further by semisynthesis or further biosynthetic engineering in the context of wider medicinal chemistry approaches to develop urgently needed novel broad-spectrum antibacterial drugs.
