Abstract: Near space hypersonic vehicles have features of strong coupling, nonlinearity and acute changes in aerodynamic parameters, which are challenging for the controller design. Active disturbance rejection control (ADRC) method does not depend on the accurate system model and has strong robustness against disturbances. This paper discusses the differences between the fractional-order PID (FOPID\(^D\)) ADRC method and the FOPID\(^D\) LADRC method for hypersonic vehicles. The FOPID\(^D\) ADRC controller in this paper consists of a tracking-differentiator (TD), a FOPID\(^D\) controller and an extended state observer (ESO). The FOPID\(^D\) LADRC controller consists of the same TD and FOPID\(^D\) controller with the FOPID\(^D\) ADRC controller and a linear extended state observer (LESO) instead of ESO. The stability of LESO and the FOPID\(^D\) LADRC method is detailed analyzed. Simulation results show that the FOPID\(^D\) ADRC method can make the hypersonic vehicle nonlinear model track desired nominal signals faster and has stronger robustness against external environmental disturbances than the FOPID\(^D\) LADRC method.

Key Words: nonlinear active disturbance rejection control, active disturbance rejection control, FOPID\(^D\) control, near space hypersonic vehicle

1 Introduction

Near space hypersonic vehicles have potential values in both military and civil applications and have received much attention in recent years [1]. Compared to the traditional aerial vehicles, hypersonic vehicles are characterized by large envelopes, high speed, low launch cost, dynamics and reusability [2]. However, their features of nonlinearity, strong coupling and aerodynamic uncertainty may lead to poor robustness properties of the closed-loop control systems, and thereby result in challenging for the robust controller design [3].

Many control methods have been discussed to achieve the flight control of the hypersonic vehicles during the last two decades. In [4], an adaptive output feedback controller was presented and applied to a linearized hypersonic vehicle model, and simulation results showed good tracking performance with the controller. A control method based on aero propulsive and elevator-to-lift couplings was proposed in [5] for an air breathing hypersonic vehicle and simulation results showed good performance of the controller. In [6], a linear parameter-varying theory based on the fractional transformation model was applied to design the controller for a hypersonic reentry vehicle, and simulations showed the accuracy and robustness of the proposed closed-loop control system for hypersonic reentry vehicles. An approximate back-stepping fault-tolerant controller was designed in [7] for a flexible air-breathing hypersonic vehicle and simulation results demonstrated good tracking properties. A composite controller was proposed in [8] for an air-breathing hypersonic vehicle to achieve the velocity and height tracking control. Duan and Li [9] summarized the limitations of some control methods on high quality and realization.

The active disturbance rejection control (ADRC) method proposed by Han [10] using the dynamic feedback compensation for the lumped unknown disturbances. Inherited from a proportion-integral-derivative (PID) method, the ADRC method is to address the weaknesses of PID and has some advantages on robustness and anti-disturbance, and has been widely used in many fields. The active disturbance rejection control (ADRC) is now considered as a powerful control strategy in dealing with large uncertainty covering unknown dynamics, external disturbance, and unknown part in coefficient of the control.

In this paper, we clarify and analysis the structure differences, characteristic differences etc. of the FOPID\(^D\) ADRC method and FOPID\(^D\) LADRC. However, the ADRC method and the LADRC method both have more tuning parameters than the traditional PID method, while the appropriate controller parameters depend on the experiences of experts. Sometime, the number of the ADRC method parameters can be reduced to one or two [16, 20]. To compare the traditional ADRC method and the LADRC method clearly, this paper does not reduce parameters.

This work is supported by National Science Foundation project (Contract No. 51206007) and Aeronautical Science Foundation of China (2013ZC51).
The remainder of the paper is organized as follows. In Section 2, the hypersonic vehicle vertical model (VM) is established. In Section 3, the differences between the FOPID\(D^\alpha\) ADRC method and FOPID\(D^\mu\) LADRC are analyzed and clarified, the stability of LESO and FOPID\(D^\alpha\) LADRC controller is detailed discussed. In section 4, verification simulation analysis results are shown. Finally, Section 5 draws conclusions.

2 Hypersonic vehicle vertical model

This paper uses the generic hypersonic vehicle (GHV) as the control object [22]. The aerodynamic equations and model parameters are obtained from [23]. The atmospheric model refers to the U.S. standard atmosphere 1976. The three-view drawing is shown in Fig. 1 and the notations related to GHV are shown in Fig. 2, according to [24].

Fuel slosh is not considered and the products of inertia are neglected in order to simplify the vehicle model.

3 Comparison of FOPID\(D^\alpha\) ADRC method and FOPID\(D^\mu\) LADRC method

3.1 FOPID\(D^\alpha\)ADRC and FOPID\(D^\mu\) LADRC controller design

The ADRC method carries over the essence of the classical PID method and assimilates characteristics of the modern control theory. The traditional ADRC method consists of a tracking-differentiator (TD), a nonlinear state error feedback control law (NLSEF) and an extended state observer (ESO). The TD can coordinate the contradiction between rapidity and overshoot, the ESO can regard all disturbances as “unknown disturbances” [25, 26]. Compared with the traditional ADRC method, the FOPID\(D^\alpha\) ADRC method results in a FOPID\(D^\alpha\) controller instead of the NLSEF. A new nonlinear FOPID\(D^\alpha\) ADRC method is proposed and adopted to hypersonic vehicle control problem, the structure diagram is shown in Fig. 3. The structure diagram of the hypersonic vehicle VM FOPID\(D^\alpha\) ADRC method is shown in Fig. 3.

In Fig. 3, the desired attack angle \(\alpha^*_1\) is the input signal, the attack angle \(\alpha\) is the output signal. TD, FOPID\(D^\alpha\) and ESO inside dashed line frame are the proposed controllers. The controlled object GHV VM is the vertical model of a hypersonic vehicle. \(\alpha_1\) and \(\alpha_2\) are the tracking signal of \(\alpha^*_1\) from the TD, respectively. \(z_1, z_2\) and \(z_3\) are the actual attack angle, the derivative signal of attack
angle and unknown disturbances obtained from ESO, respectively. \( u_0 \) is the ideal control variable and \( u \) is the actual control variable.

The TD discrete form can be described by the following equations:

\[
\begin{align*}
\alpha_1(k+1) &= \alpha_1(k) + h(z_1(k) - 2r_1\alpha_1(k)) \\
\alpha_2(k+1) &= \alpha_2(k) + h(-r_2(\alpha_1(k) - \alpha_2(k)) - 2r_2\alpha_2(k))
\end{align*}
\]

where \( \alpha_1(k) \) and \( \alpha_2(k+1) \) denote estimated attack angle value of current time and next time, respectively, \( \alpha_1(k) \) and \( \alpha_2(k+1) \) are derivatives of \( \alpha_1(k) \) and \( \alpha_2(k+1) \), respectively, \( r_1 \) and \( h \) represent speed factor and filtering factor, respectively. The larger \( r_1 \) values, the shorter the transition processes, the faster the response. The larger \( h \) values, the better for the noise filtering.

The FOPID\(^a \) equation is shown as follows:

\[
G_i(s) = \frac{U(s)}{E(s)} = K_p + \frac{K_i}{s^\lambda} + K_d s^{\mu}
\]

Where \( \lambda \) and \( \mu \) are restricted to \( 0 < \lambda, \mu < 1 \). The FOPID\(^a \) controller increments two degrees of freedom variables \( \lambda \) and \( \mu \), thus making the control affect more precisely and stable. The structure diagram of the FOPID\(^a \) controller is shown in Fig. 4.

In Fig. 4, \( e \) and \( u \) represent the error and control variable, respectively, \( e \) passes through \( K_0 \), FO integral method and FO derivative method to get \( e_1, e_2 \) and \( e_3 \), respectively.

The ESO in Fig. 3 is a third-order system and the extended state observer can be described by the following equation:

\[
\begin{align*}
e_{10} &= z_1 - \alpha \\
z_1 &= z_1 - \beta_{01} e_{10} \\
z_2 &= z_2 - \beta_{02} |e_{10}|^{1/2} \text{sign}(e_{10}) + b_0 u \\
z_3 &= -\beta_{03} |e_{10}|^{1/2} \text{sign}(e_{10})
\end{align*}
\]

where \( \beta_{01}, \beta_{02} \) and \( \beta_{03} \) are adjustable parameters with different values, which can affect the effect of signal observed, \( z_1 \) and \( z_2 \) are the estimated attack angle \( \alpha \) and estimated derivative signal of attack angle \( \alpha \), respectively, \( z_3 \) is the estimated "unknown disturbances" of GHV VM and \( b_0 \) is to affect the compensation of unknown disturbances. With appropriate values of \( \beta_{01}, \beta_{02} \) and \( \beta_{03} \), the ESO can have good effect.

The LADRC method and the FOPID\(^a \) ADRC method are almost the same, except for the ESO method. The ESO of the FOPID\(^a \) ADRC method is nonlinear, while the ESO of the LADRC method is linear (LESO), which can be shown as follows:

![Fig. 5: The structure diagram of the hypersonic vehicle VM LADRC method](image)

In Fig. 5, the LESO is different from the ESO in Fig. 3 and the other parts are the same, and the meanings of variables are the same as those in Fig. 3. The ADRC method and the LADRC method both have more tuning parameters than the traditional PID method, while the appropriate controller parameters depend on the experiences of experts. Sometime, the number of the ADRC method parameters can be reduced to one or two [16, 20]. To compare the traditional ADRC method and the LADRC method clearly, this paper does not reduce parameters.

### 3.2 Analysis of FOPID\(^a \) ADRC method

We have analyzed the stability of the second-order ESO and the FOPID\(^a \) ADRC method [28]. The stability analysis of LESO and the FOPID\(^a \) LADRC method is the same.

#### 3.2.1 The stability analysis of LESO

The pitch channel equation (1) can be written as follows:

\[
\begin{align*}
\dot{\alpha}_1 &= \alpha_2 \\
\dot{\alpha}_2 &= f(\cdot) + b_0 u
\end{align*}
\]

Suppose the first-order derivative of \( f(\cdot) \) exists and is bounded and define \( \alpha_1 = f(\cdot), \dot{f}(\cdot) = \dot{f}(\cdot) \), (6) can be extended to (7). The LESO for (6) is (8).

\[
\begin{align*}
\dot{c}_1 &= c_2 - \alpha_1 \\
\dot{c}_2 &= c_2 - \beta_{03} c_1 \\
\dot{c}_3 &= c_2 - \beta_{02} c_1 + b_0 u \\
\dot{c}_4 &= -\beta_{03} c_1
\end{align*}
\]

Define \( e_1 = z_1 - \alpha_1, e_2 = z_2 - \alpha_2, e_3 = z_3 - \alpha_1 \), from (7) and (8), the error equations can be shown as follows:
\begin{equation}
\dot{e} = A e + B u
\end{equation}

\begin{align*}
A & = \\
& = \begin{pmatrix} -\beta_{o1} & 1 & 0 \\ -\beta_{o2} & 0 & 1 \\ -\beta_{o3} & 0 & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 0 \\ 0 \\ -1 \end{pmatrix}, \quad u = f_u(t) 
\end{align*}

The characteristic equation of (9) is:

\begin{equation}
s^3 + \beta_{o1}s^2 + \beta_{o2}s + \beta_{o3} = 0
\end{equation}

When \(\beta_{o1}\beta_{o2} > \beta_{o3}\), the LESO is stable. When \(f(\cdot)\) is step function or ramp function, LESO is able to track \(\alpha_i, \alpha_j, \alpha_k\). When \(f(\cdot)\) is acceleration function, LESO is not able to track the desired signal.

\begin{align*}
\Delta \alpha &= \frac{s(s^2 + \beta_{o1}s + \beta_{o2}) + b_1s(K_{p1} + K_{s1}s^{-1} + K_{d1}s^2) + b_3s(s + \beta_{o1})(K_{p2} + K_{s2}s^{-1} + K_{d2}s^2)}{s^2 + \beta_{o1}s + \beta_{o2}s + \beta_{o3}} \\
& + \frac{b_1s(K_{p1} + K_{s1}s^{-1} + K_{d1}s^2) + b_3s(K_{p2} + K_{s2}s^{-1} + K_{d2}s^2)}{s^2 + \beta_{o1}s + \beta_{o2}s + \beta_{o3}} + \frac{b_1s(K_{p1} + K_{s1}s^{-1} + K_{d1}s^2)}{s^2 + \beta_{o1}s + \beta_{o2}s + \beta_{o3}} \\
\Delta \alpha - \Delta \alpha &= \frac{s(s^2 + \beta_{o1}s + \beta_{o2}) + b_1s(K_{p1} + K_{s1}s^{-1} + K_{d1}s^2) + b_3s(s + \beta_{o1})(K_{p2} + K_{s2}s^{-1} + K_{d2}s^2)}{s^2 + \beta_{o1}s + \beta_{o2}s + \beta_{o3}} \\
& + \frac{b_1s(K_{p1} + K_{s1}s^{-1} + K_{d1}s^2) + b_3s(s + \beta_{o1})(K_{p2} + K_{s2}s^{-1} + K_{d2}s^2)}{s^2 + \beta_{o1}s + \beta_{o2}s + \beta_{o3}} + \frac{b_1s(K_{p1} + K_{s1}s^{-1} + K_{d1}s^2)}{s^2 + \beta_{o1}s + \beta_{o2}s + \beta_{o3}} \\
& + \frac{b_1s(K_{p1} + K_{s1}s^{-1} + K_{d1}s^2) + b_3s(s + \beta_{o1})(K_{p2} + K_{s2}s^{-1} + K_{d2}s^2) + b_1s(K_{p1} + K_{s1}s^{-1} + K_{d1}s^2)}{s^2 + \beta_{o1}s + \beta_{o2}s + \beta_{o3}} \\
& + \frac{b_1s(K_{p1} + K_{s1}s^{-1} + K_{d1}s^2) + b_3s(s + \beta_{o1})(K_{p2} + K_{s2}s^{-1} + K_{d2}s^2) + b_1s(K_{p1} + K_{s1}s^{-1} + K_{d1}s^2)}{s^2 + \beta_{o1}s + \beta_{o2}s + \beta_{o3}}
\end{align*}

So the characteristic equation of (14) is:

\begin{equation}
\frac{s^2 + \beta_{o1}s + \beta_{o2}s + \beta_{o3}}{s^2 + \beta_{o1}s + \beta_{o2}s + \beta_{o3}} = 0
\end{equation}

Therefore, when parameters \(K_{p1}, K_{s1}, K_{d1}, K_{p2}, K_{s2}, K_{d2}\) can make all roots of characteristic equation (11) are on the left half-plane, the FOPI-D^\mu LADRC controller for hypersonic vehicles is stable.

### 4 Comparative simulation of FOPI-D^\mu ADRC and FOPI-D^\mu LADRC

Taking the longitudinal model of hypersonic vehicle as an example, the three modules of the auto disturbance rejection structure are tracking the differential device, the fractional order PID and the linear extended state observer. In order to compare and analyze the characteristics of the linear active disturbance rejection controller, the same structure of the active disturbance rejection controller is simulated, which is followed by the tracking controller, the fractional order PID and the extended state observer.

4.1 Comparative simulation of normal operating conditions

The angle of attack of the control system is a continuous square wave signal with amplitude of 10 degrees. The simulation results are shown in Fig. 6.

![Graph](image-url)

(a) Time / s

(b) Time / s

\[(\text{Input} \quad \text{Nonlinear} \quad \text{Linear})\]
In Fig. 6, the 'Input' represents the continuous square wave signal; 'Nonlinear' is a nonlinear active disturbance rejection controller. 'Linear' is a linear active disturbance rejection controller. Two control structures can make the output of the attack angle of attack fast tracking input signal, with a very small steady-state error and overshoot. The adjustment time of linear structure and nonlinear structure is 0.322s and 0.296s. Under the condition of no external disturbance, the control effect of the nonlinear active disturbance rejection control structure is better than that of the linear active disturbance rejection controller.

4.2 Electronic Image Files (Optional)

To show the anti-disturbance ability of the two controllers, the input signal is still a continuous wave signal with amplitude of 10 degrees. When the input signal is 2S and 7S, the interference signal is added. The interference signal amplitude is 90, and the duration is 140ms. The disturbance can be seen as an impact of the wind. The simulation results are shown in Fig. 7.

In Fig. 7, the meaning of each signal is the same as that of fig. 6. In Fig. 7(a), the two methods can track the reference signal rapidly. Two control structures are able to effectively track the input attack angle signal. In Fig. 7(b), the responses of ADRC method and LADRC method both have less than two percent changes lasting less than 1 s at 2 s, when subjected to external disturbance. But, the response of ADRC method with respect to the disturbance is more stable. Therefore, for hypersonic vehicle vertical model, the nonlinear controller demonstrates nominal better anti-disturbance ability and stronger robustness than the linear controller in some degree.

5 Conclusions

In this paper, by combining FOPI'D P controller and the traditional ADRC method (TD, NLSEF and ESO), a FOPI'D P ADRC controller is designed for hypersonic vehicles. By replacing ESO with LESO, we obtain the FOPID P LADRC controller. Then the differences of the FOPI'D P ADRC method and FOPID P LADRC are firstly clarified and analyzed. The stability of LESO and FOPID P LADRC controller for hypersonic vehicle vertical model is analyzed. The experiment results show that the FOPI'D P ADRC method performs better than the FOPID P LADRC method.
