Abstract—We demonstrate broadband wavelength conversion of 10 Gb/s RZ-OOK signals using a cross phase modulation based integrated nonlinear optical loop mirror on silicon-on-insulator.

I. INTRODUCTION

Nonlinear optical loop mirror (NOLM) has been studied for several decades and it has many applications in high speed optical signal processing [1], wavelength conversion [2], pulse generation [3], de-multiplexing [4] and so on. On the other side, since silicon is a good nonlinear media, it can be used to generate and process optical signals in low-cost ultracompact chips at high speeds based on nonlinear optical effects [5]. In order to satisfy the need of integration of optical system, in this paper, we firstly designed and fabricated on-chip silicon NOLM and demonstrated the error-free wavelength conversion of 10 Gb/s return-to-zero on-off keying (RZ-OOK) signals with a wavelength range from 1535nm to 1565nm using cross-phase modulation (XPM) based NOLM system.

II. DEVICE AND EXPERIMENTS

A. XPM based NOLM and Experiments

The structure we present in this paper is XPM based NOLM, whose principle is explained in [6]. The schematic of integrated NOLM in silicon on insulator (SOI) is shown in Fig 1 (b). The input light is coupled into the integrated silicon chip by vertical grating couplers (VGCs). VGCs are designed for C-

band TE mode with a bandwidth of 15nm and the coupling loss per VGC is around -7.5dB by measurement. Port 2 and port 3 are connected with a multi-mode interferometer (MMI) coupler with the coupling ratio of 50/50, and the waveguide in the loop is 1.25 cm. The waveguide consists 0.314 mm bend waveguide with bend radius of 10 μm and 12.186 mm straight waveguide. Port 1 and port 4 are added at the beginning and end of the loop by two 50/50 y-branch power splitters working as the input port of the pump pulses and port for detection. The continuous-wave (CW) probe is launched through port 2 to the NOLM and port 3 is the output of the device. The device was fabricated using e-beam lithography with a single etch and the size is around 2.65 mm \times 0.41 mm. The nonlinear effect occurs in the silicon nanowire loop, whose cross-section is shown in Fig 1 (a). The silicon nanowires have a width of 500 nm and height of 220 nm, which is designed mostly to support TE fundamental mode. All the components sit on top of buried oxide layer with the thickness of 3 μm and are covered by a 2 μm oxide cladding. The measured propagation loss of silicon waveguide is about -2.7 dB/cm, so the total loss of the NOLM structure from port 1 to port 3 is measured as around -27 dB.

The experimental setup is illustrated in Fig 1. The pump is RZ-OOK signals with a PRBS length of $2^{31}-1$, which is generated by a mode lock laser with the frequency of 9.95328 GHz and the pulse width of 5 ps. The pulses are then modulated by a LiNbO₃-based Mach-Zehnder modulator (MZ) driven by a pulse pattern generator (PPG). Then the modulated

pump signals are amplified by a high power EDFA and filtered by a WDM to remove the amplified spontaneous emission (ASE) noise. After amplifying and filtering, the pulses are broadened to 15ps and therefore the duty cycle of pump signals launched into the chip is 15%. The continuous wave (CW)

probe light is also amplified, filtered and coupled into the chip. It combines with the pump signals in the loop to generate XPM effect. The output signals of NOLM are at last filtered by another WDM to remove the pump signals and the wavelength converted signals are received and detected using a pre-amplified receiver and a digital communications analyzer (DCA). In the experiment, the central wavelength of the pump is fixed to 1550 nm and we vary the probe wavelength from 1535 nm to 1565 nm and bit error rate (BER) measurements are obtained for a probe wavelength of 1535 nm, 1540nm, 1560nm, and 1565nm.

B. Results

Fig. 2 shows the spectral output of the NOLM for different probe wavelengths. The average power into the silicon loop of pump signals and probe are 21 dBm and 18 dBm, respectively. We observed XPM-based broadening around the central wavelength of the probe as the probe wavelength is tuned over a 30 nm range.

In order to verify the performance of wavelength conversion, we measure the BER of the wavelength converted signals, see Fig. 3. We obtained error free operation and observed a clearly opened eye-diagram in a wavelength range of 30nm with the power penalties of less than 2.8 dB.

III. CONCLUSION

We have presented the integrated NOLM on SOI platform for the first time and successfully demonstrated XPM-based wavelength conversion for 10 Gb/s RZ-OOK signals. The converted RZ-OOK signal exhibits no error floor with a power penalty less than 2.8 dB. We believe that XPM-based wavelength conversion in an integrated NOLM will provide an advancement toward the integration of all-optical high-speed optical networking systems.
