The Strathprints institutional repository (https://strathprints.strath.ac.uk) is a digital archive of University of Strathclyde research outputs. It has been developed to disseminate open access research outputs, expose data about those outputs, and enable the management and persistent access to Strathclyde's intellectual output.
Visualising Speech: Identification of Atypical Tongue-Shape Patterns in the Speech of Children with Cleft Lip and Palate Using Ultrasound Technology

Background
Gibbon (2004) identifies 8 distinct error types in the speech of people with cleft lip and palate (CLP)¹.

EPG measures tongue-palate contact, but is expensive and logistically difficult. In contrast, ultrasound tongue imaging (UTI) is cheaper, and can image the posterior articulations (such as pharynges) not visible with EPG which are common in CLP.

Can the eight error types made visible with ultrasound? EPG measures tongue-palate contact, but is expensive and logistically difficult. In contrast, ultrasound tongue imaging (UTI) is cheaper, and can image the posterior articulations (such as pharynges) not visible with EPG which are common in CLP.

Method
To date, data has been collected from 35 children aged 3 to 12 with CLP.

Data are spoken materials from the CLEFTNET protocol²:
- /Ca/ x 10
- Minimal sets (e.g. a sip, a ship, a kip, a tip)
- Sentences from the GOS.SP.ASS. 98³ (e.g. (Happy) Karen is making a cake)

Analysis using ultrasound-assisted transcription to identify Gibbon’s 8 error types:
- Live by the clinician collecting the data
- Offline but in Real-time by two ultrasound trained clinicians
- Offline in slow motion by two ultrasound trained clinicians

Results: Errors Revealed by Ultrasound

Target sounds indicated in /brackets/. Mid-sagittal views show the tongue tip to the right. Abnormal timing and increased variability are also identifiable with UTI, but not shown here.

Results: Aided Transcription

From early analysis of data gathered so far:
- 60.3% of consonants were produced correctly
- 60.1% of consonants in error were imageable by ultrasound
- Non-imageable errors were non-lingual: e.g. nasalised, fricated/loss of pressure, glottal reinforcement

Inter-rater reliability for offline real-time transcription was “good” using Cohen’s kappa (k=.716, p<.0005).

Discussion
- All of Gibbon’s errors have been identified in our data using ultrasound aided transcription
- Additionally, retroflex errors were identified using UTI
- Identification of some error types may change diagnosis and therefore intervention choice
- Ultrasound is cheaper and more convenient than EPG as it does not require individualised plates or advance planning; children were able to opt in to the project while at routine appointments
