Abstract This paper reports the boundedness and stability of highly nonlinear hybrid neutral stochastic differential delay equations (NSDDEs) with multiple delays. Without imposing linear growth condition, the boundedness and exponential stability of the exact solution are investigated by Lyapunov functional method. In particular, using the M-matrix technique, the mean square exponential stability is obtained. Finally, three examples are presented to verify our results.

Keywords Hybrid delay systems, neutral stochastic systems, multiple delays, highly nonlinear.

1 Introduction

Since continuous-time Markov chains were introduced to describe stochastic systems which undergo abrupt changes in their parameters and structures, hybrid stochastic differential equations (SDEs) have been widely used in engineering and science. Moreover, SDDEs are often used to investigate systems whose evolution depends on not only the present state but also the past state [1–5]. Boundedness and stability are two of the most basic issues in analyzing hybrid SDDEs. However, most of the papers in this field only considered systems whose coefficients are bounded by linear functions [6–11]. Recently, some significant results are obtained for highly nonlinear stochastic delay systems. For example, Hu et al. [12] investigated the boundedness and stability of hybrid SDDEs without the linear growth condition. While Hu et al. [13] studied the robust stability and boundedness of nonlinear hybrid SDDEs by the method of M-matrix. Fei et al. [14] established delay dependent criteria for highly nonlinear hybrid SDDEs under the polynomial growth condition. Moreover, Fei et al. [15] discussed structured robust stability and boundedness under highly nonlinear condition by introducing a new Lyapunov function.

Many stochastic systems which not only depend on present and past states but also involve derivatives with delays are modeled by neutral stochastic differential delay equations. Although, extensive literature can be found in this area, we mention a few of them herein [16–23]. Also, many researchers have made efforts in regard to the stability of highly nonlinear neutral stochastic systems. For example, Luo et al. [24] established criteria for exponential stability of neutral SDEs that exhibit a time-dependent delay.

^{*} Corresponding author (email: wyfei@ahpu.edu.cn)

Furthermore, Song and Shen [25] investigated stability criteria that not only covers a large class of highly nonlinear neutral stochastic functional differential equations but also handles general stability issues. Moreover, the stability of NSDDEs with Markov switching, also known as hybrid NSDDEs, is studied by many researchers. For example, Kolmanovskii et al. [26] established a fundamental theory for hybrid NSDDEs and discussed the boundedness and stability of the systems. Mao et al. [27] investigated almost sure stability of a class hybrid NSDDEs. Furthermore, Li and Deng [28] established a criterion for general decay rate of almost sure stability of hybrid NSDDEs with lévy noise using Lyapunov functional and Mmatrix techniques. However, all the functions V(x,t,i) in these references are required to have the same degree for each $i \in S$, which may not be satisfied by hybrid NSDDEs that have different structures in different modes. Moreover, neutral stochastic systems may not depend only on single delay. Zhao et al. [29] provided motivation with regards to the study of stability of linear neutral systems with multiple delays. Chen et al. [30] investigated delay dependent exponential stability of multiple time-varying delays neutral stochastic systems. For more information on the stability of neutral systems with multiple delays, we refer the reader to [31-33]. However, it is crucial to observe that all the multiple time delays systems discussed in these papers are linear systems. Considering [12, 24, 25, 28, 30], herein, we extend the linear multiple delays neutral stochastic systems to highly nonlinear hybrid NSDDEs. By applying the Lyapunov functional technique, a sufficient condition for the stability of highly nonlinear NSDDEs with multiple delays is established under mild conditions. In particular, mean square exponential stability is investigated using M-matrix method.

The important features of this paper are as follows:

• In establishing the theory on the boundedness and stability of hybrid NSDDEs with highly nonlinear coefficients, multiple delays are taken into consideration.

• New mathematical techniques are developed to handle multiple delays NSDDEs under highly nonlinear growth condition. For example, a general Lyapunov function is introduced.

• H_{∞} stability and almost sure exponential stability are discussed.

The remaining sections of this paper are structured as follows: In Section 2, some preliminary definitions, assumptions and a key lemma are presented. Section 3 mainly discusses the existence and uniqueness of solutions of highly nonlinear NSDDEs with multiple delays. Also, using the Lyapunov functional and M-matrix methods, the boundedness and stability criteria for hybrid NSDDEs are discussed. In Section 4, three examples are given to illustrate the applicability of our results. Finally, a conclusion is drawn in Section 5.

2 Preliminary

Let $B(t) = (B_1(t), \dots, B_d(t))^T$ be a *d*-dimensional Brownian motion defined on the probability space $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}_{t \ge 0}, P)$, where the filtration $\{\mathcal{F}_t\}_{t \ge 0}$ satisfies the usual conditions (i.e. it is right continuous and \mathcal{F}_0 contains all *P*-null sets). Let $\{r(t), t \ge 0\}$ be a right-continuous Markov chain on the probability space taking values in a finite state space $S = \{1, 2, \dots, N\}$ with generator $\Gamma = (\gamma_{ij})_{N \times N}$. (For the detail of Γ we refer the reader to [5, page 47]). With regard to what follows, we assume that the Markov chain $r(\cdot)$ is independent of the Brownian motion $B(\cdot)$.

Let $C(R^n \times [-\tau, \infty); R_+)$ denote the family of all continuous functions from $R^n \times [-\tau, \infty)$ to R_+ . Let

 $f: R^n \times \cdots \times R^n \times S \times R_+ \to R^n$ and $g: R^n \times \cdots \times R^n \times S \times R_+ \to R^{n \times d}$

be Borel measurable functions. Let $\delta_l : R_+ \to [0, \tau_l], l = 1, \cdots, m$ denote the variable time delay such that $\dot{\delta}_l(t) := d\delta_l(t)/dt \leq \bar{\delta}_l < 1$ for all $t \geq 0$.

Herein, we consider the following neutral hybrid NSDDE with multiple delays

$$d[X(t) - \Lambda(X(t - \delta_1(t)), r(t), t)] = f(X(t), X(t - \delta_1(t)), \cdots, X(t - \delta_m(t)), r(t), t)dt + g(X(t), X(t - \delta_1(t)), \cdots, X(t - \delta_m(t)), r(t), t)dB(t),$$
(1)

on $t \ge 0$ with initial data

$$\{X(t): -\tau \leqslant t \leqslant 0\} = \xi \in C([-\tau, 0]; \mathbb{R}^n) \quad \text{and} \quad r(0) = i_0 \in S,$$

$$\tag{2}$$

where $\tau = \max\{\tau_l : l = 1, \dots, m\}$, $\Lambda : \mathbb{R}^n \times S \times \mathbb{R}_+ \to \mathbb{R}^n$, $C([-\tau, 0]; \mathbb{R}^n)$ denotes the family of continuous functions ξ from $[-\tau, 0] \to \mathbb{R}^n$ with the norm $\|\xi\| = \sup_{-\tau \leq s \leq 0} |\xi(s)|$. We also assume that $f(0, \dots, 0, i, t) = g(0, \dots, 0, i, t) = \Lambda(0, i, t) = 0$.

Let $C^{2,1}(\mathbb{R}^n \times S \times \mathbb{R}_+; \mathbb{R}_+)$ denote the family of nonnegative functions V(x, i, t) on $\mathbb{R}^n \times S \times \mathbb{R}_+$, which are continuously twice differentiable in x and once in t, and define an operator $LV: \mathbb{R}^n \times \cdots \times \mathbb{R}^n \times S \times \mathbb{R}_+ \to \mathbb{R}$ by

$$\begin{split} LV(x - \Lambda(y_1, i, t), y_1, \cdots, y_m, i, t) \\ &= V_t(x - \Lambda(y_1, i, t), i, t) + V_x(x - \Lambda(y_1, i, t), i, t) f(x, y_1, \cdots, y_m, i, t) \\ &+ \frac{1}{2} \text{trace}[g^T(x, y_1, \cdots, y_m, i, t) V_{xx}(x - \Lambda(y_1, i, t), i, t) g(x, y_1, \cdots, y_m, i, t)] \\ &+ \sum_{j=1}^N \gamma_{ij} V(x - \Lambda(y_1, i, t), j, t), \end{split}$$

where $V_t(x, i, t) = \frac{\partial V(x, i, t)}{\partial t}$, $V_x(x, i, t) = \left(\frac{\partial V(x, i, t)}{\partial x_1}, \cdots, \frac{\partial V(x, i, t)}{\partial x_n}\right)$, $V_{xx}(x, i, t) = \left(\frac{\partial^2 V(x, i, t)}{\partial x_k \partial x_l}\right)_{n \times n}$. Assumption 1. For each integer $H \ge 1$, we assume there exists a positive constant \bar{K}_H such that

$$|f(x, y_1, \cdots, y_m, i, t) - f(\bar{y}, \bar{y}_1, \cdots, \bar{y}_m, i, t)|^2 \vee |g(x, y_1, \cdots, y_m, i, t) - g(\bar{x}, \bar{y}_1, \cdots, \bar{y}_m, i, t)|^2 \\ \leqslant \bar{K}_H(|x - \bar{x}|^2 + \sum_{l=1}^m |y_l - \bar{y}_l|^2)$$

for those $x, \bar{x}, y_l, \bar{y}_l \in \mathbb{R}^n$ with $|x| \vee |\bar{x}| \vee |y_l| \vee |\bar{y}_l| \leq H$ and all $(i, t) \in S \times \mathbb{R}_+$. Assumption 2. We assume there exist constants $\kappa_i \in (0, 1)$ such that

$$|\Lambda(a, i, t) - \Lambda(b, i, t)| \leqslant \kappa_i |a - b| \tag{3}$$

for all $a, b \in \mathbb{R}^n$, and $\Lambda(0, i, t) = 0$. Furthermore, we assume that $\kappa = \max\{\kappa_i, i = 1, \dots, N\}$.

We now state the following lemma which plays crucial role in this paper.

Lemma 1. Define the quasi polynomial function $U(x) = a_h |x|^{\beta_h} + \cdots + a_1 |x|^{\beta_1}, x \in \mathbb{R}^n$, where |x| is the Euclidean norm of $x, a_i \ge 0, i = 1, \cdots, h-1, \beta_h \ge \beta_{h-1} \ge \cdots \ge \beta_1 \ge 0$ and $a_h > 0$. Let $\tau > 0$ and δ be a differentiable function from $R_+ \to [0, \tau]$ such that $d\delta(t)/dt \le \overline{\delta} < 1$. Assume $|\Lambda(X(t), r(t), t)| \le \kappa |X(t)|, X(t) : [-\tau, \infty) \to \mathbb{R}^n$ is a continuous function, and r(t) is a Markov chain on the state space S, where $X(t) = \xi(t), t \in [-\tau, 0], 0 < \kappa < 1$. Fixing $\varepsilon > 0$ arbitrarily, we have the following conclusions: (i)

$$\int_{0}^{T} e^{\varepsilon t} U(X(t-\delta(t))) dt \leq \frac{e^{\varepsilon \tau}}{1-\overline{\delta}} \int_{-\tau}^{0} U(\xi(t)) dt + \frac{e^{\varepsilon \tau}}{1-\overline{\delta}} \int_{0}^{T} e^{\varepsilon t} U(X(t)) dt, \quad \forall T > 0.$$

$$\tag{4}$$

(ii)

$$\int_0^T e^{\varepsilon t} U(X(t) - \Lambda(X(t - \delta(t)), r(t), t)) dt \leq \frac{e^{\varepsilon \tau}}{1 - \overline{\delta}} \int_{-\tau}^0 U(\xi(t)) dt + C_\tau \int_0^T e^{\varepsilon t} U(X(t)) dt, \quad \forall T > 0,$$

where $C_{\tau} = \max\{\frac{\kappa e^{\varepsilon\tau}}{1-\delta} + (1-\kappa)^{1-\beta_h}, \frac{e^{\varepsilon\tau}}{1-\delta} + 1\}.$ **Proof.** For $p \ge 0$, it is easy to show that

$$\int_0^T e^{\varepsilon t} |X(t-\delta(t))|^p dt \leqslant e^{\varepsilon \tau} \int_0^T e^{\varepsilon (t-\delta(t))} |X(t-\delta(t))|^p dt \leqslant \frac{e^{\varepsilon \tau}}{1-\overline{\delta}} \int_{-\tau}^T e^{\varepsilon s} |X(s)|^p ds$$

Mingxuan Shen, et al. Sci China Inf Sci 4

$$\leq \frac{e^{\varepsilon\tau}}{1-\bar{\delta}} \int_{-\tau}^{0} |\xi(s)|^{p} ds + \frac{e^{\varepsilon\tau}}{1-\bar{\delta}} \int_{0}^{T} e^{\varepsilon s} |X(s)|^{p} ds.$$
(5)

By the definition of U(x), we obtain

$$\begin{split} &\int_0^T e^{\varepsilon t} U(X(t-\delta(t)))dt = \int_0^T e^{\varepsilon t} (a_h | X(t-\delta(t))|^{\beta_h} + \dots + a_1 | X(t-\delta(t))|^{\beta_1})dt \\ &\leqslant \frac{e^{\varepsilon \tau}}{1-\overline{\delta}} \int_{-\tau}^0 a_h |\xi(s)|^{\beta_h} + \dots + a_1 |\xi(s)|^{\beta_1} ds + \frac{e^{\varepsilon \tau}}{1-\overline{\delta}} \int_0^T e^{\varepsilon s} (a_h | X(s)|^{\beta_h} + \dots + a_1 | X(s)|^{\beta_1}) ds \\ &= \frac{e^{\varepsilon \tau}}{1-\overline{\delta}} \int_{-\tau}^0 U(\xi(s)) ds + \frac{e^{\varepsilon \tau}}{1-\overline{\delta}} \int_0^T e^{\varepsilon s} U(X(s)) ds, \end{split}$$

establishing (i). Next, we establish the assertion (ii). For $p \ge 1$, we apply the inequality

$$(u+v)^p \leqslant (1+\varpi)^{p-1}(u^p+\varpi^{1-p}v^p) \quad \forall u,v \ge 0, \ p \ge 1, \ \varpi > 0,$$

it is easy to see that

$$|X(t) - \Lambda(X(t - \delta(t)), r(t), t)|^{p} \leq (1 + \varpi)^{p-1} (|X(t)|^{p} + \varpi^{1-p} |\Lambda(X(t - \delta(t)), r(t), t)|^{p}).$$

Setting $\varpi = \frac{\kappa}{1-\kappa}$, we derive

$$|X(t) - \Lambda(X(t - \delta(t)), r(t), t)|^{p} \leq (1 - \kappa)^{1-p} |X(t)|^{p} + \kappa^{1-p} |\Lambda(X(t - \delta(t)), r(t), t)|^{p} \leq (1 - \kappa)^{1-p} |X(t)|^{p} + \kappa |X(t - \delta(t))|^{p},$$
(6)

which, together with (5), shows that

$$\int_{0}^{T} e^{\varepsilon t} |X(t) - \Lambda(X(t - \delta(t)), r(t), t)|^{p} dt \leq (1 - \kappa)^{1 - p} \int_{0}^{T} e^{\varepsilon t} |X(t)|^{p} dt + \kappa \int_{0}^{T} e^{\varepsilon t} |X(t - \delta(t))|^{p} dt$$

$$\leq \frac{\kappa e^{\varepsilon \tau}}{1 - \overline{\delta}} \int_{-\tau}^{0} |\xi(t)|^{p} dt + \frac{\kappa e^{\varepsilon \tau}}{1 - \overline{\delta}} \int_{0}^{T} e^{\varepsilon t} |X(t)|^{p} dt + (1 - \kappa)^{1 - p} \int_{0}^{T} e^{\varepsilon t} |X(t)|^{p} dt$$

$$= \frac{\kappa e^{\varepsilon \tau}}{1 - \overline{\delta}} \int_{-\tau}^{0} |\xi(t)|^{p} dt + \left[\frac{\kappa e^{\varepsilon \tau}}{1 - \overline{\delta}} + (1 - \kappa)^{1 - p}\right] \int_{0}^{T} e^{\varepsilon t} |X(t)|^{p} dt. \tag{7}$$

Noting that $0 < 1 - \kappa < 1$ and $1 - p \leq 0$, we have $(1 - \kappa)^{1-p} \leq (1 - \kappa)^{1-\beta_h}$, $\forall p \leq \beta_h$. Thus, from (7), the following inequality holds for all $1 \leq p \leq \beta_h$,

$$\int_{0}^{T} e^{\varepsilon t} |X(t) - \Lambda(X(t - \delta(t)), r(t), t)|^{p} dt$$

$$\leq \frac{\kappa e^{\varepsilon \tau}}{1 - \overline{\delta}} \int_{-\tau}^{0} |\xi(t)|^{p} dt + \left[\frac{\kappa e^{\varepsilon \tau}}{1 - \overline{\delta}} + (1 - \kappa)^{1 - \beta_{h}}\right] \int_{0}^{T} e^{\varepsilon t} |X(t)|^{p} dt.$$
(8)

For $0 \leq p < 1$, by the elementary inequality $(u+v)^p \leq u^p + v^p, \forall u, v \geq 0$, we obtain

$$\begin{split} \int_0^T e^{\varepsilon t} |X(t) - \Lambda(X(t - \delta(t)), r(t), t)|^p dt &\leqslant \frac{\kappa^p e^{\varepsilon \tau}}{1 - \bar{\delta}} \int_{-\tau}^0 |\xi(t)|^p dt + \left(\frac{\kappa^p e^{\varepsilon \tau}}{1 - \bar{\delta}} + 1\right) \int_0^T e^{\varepsilon t} |X(t)|^p dt \\ &\leqslant \frac{e^{\varepsilon \tau}}{1 - \bar{\delta}} \int_{-\tau}^0 |\xi(t)|^p dt + \left(\frac{e^{\varepsilon \tau}}{1 - \bar{\delta}} + 1\right) \int_0^T e^{\varepsilon t} |X(t)|^p dt. \end{split}$$

Thus, together with (8) and the definition of U(x), we see that

$$\int_{0}^{T} e^{\varepsilon t} U(X(t) - \Lambda(X(t - \delta(t)), r(t), t)) dt$$

=
$$\int_{0}^{T} e^{\varepsilon t} (a_{h} | X(t) - \Lambda(X(t - \delta(t)), r(t), t) |^{\beta_{h}} + \dots + a_{1} | X(t) - \Lambda(X(t - \delta(t)), r(t), t) |^{\beta_{1}}) dt$$

$$\leq \frac{e^{\varepsilon\tau}}{1-\bar{\delta}} \int_{-\tau}^{0} a_h |\xi(t)|^{\beta_h} + \dots + a_1 |\xi(t)|^{\beta_1} dt + C_\tau \int_0^T e^{\varepsilon t} (a_h |X(t)|^{\beta_h} + \dots + a_1 |X(t)|^{\beta_1}) dt$$
$$= \frac{e^{\varepsilon\tau}}{1-\bar{\delta}} \int_{-\tau}^0 U(\xi(t)) dt + C_\tau \int_0^T e^{\varepsilon t} U(X(t)) dt.$$

Hence, the proof is complete. \Box

Assumption 3. We assume that there exist three functions $V \in C^{2,1}(\mathbb{R}^n \times S \times \mathbb{R}_+; \mathbb{R}_+)$, $U_1, U_2 \in U$, as well as nonnegative constants, a_1, a_2, c_l , where $l = 1, \dots, m$ and $a_2 > \sum_{l=1}^m c_l$, such that

$$U_1(x,t) \leqslant V(x,i,t) \leqslant U_2(x,t), \quad \forall (x,i,t) \in \mathbb{R}^n \times S \times \mathbb{R}_+,$$
(9)

and

$$LV(x - \Lambda(y_1, i, t), y_1, \cdots, y_m, i, t) \leq a_1 - a_2 U_2(x, t) + \sum_{l=1}^m c_l (1 - \bar{\delta}_l) U_2(y_l, t - \delta_l(t)),$$

for all $x, y_1, \dots, y_m \in \mathbb{R}^n$ and $(i, t) \in S \times \mathbb{R}_+$.

3 Boundedness and Stability

Using the notations and assumptions introduced in the previous section, we first establish the existence and uniqueness of a solution of the system (1) in this section.

Theorem 1. Suppose Assumptions 1, 2 and 3 hold, then for any initial data given by (2), we have the following assertions:

(i) There exists a unique global solution X(t) to the the hybrid NSDDE (1) on $t \in [-\tau, \infty)$.

(ii) The solution obtained in (i) has the property that

$$\limsup_{t \to \infty} \frac{1}{t} \int_0^t EU_2(X(s), s) ds \leqslant \frac{a_1}{a_2 - \sum_{l=1}^m c_l}.$$
 (10)

Proof: Since the coefficients of the hybrid NSDDE (1) are locally Lipschitz continuous, it follows that for any given initial data (2) and $r_0 \in S$ arbitrarily, there exists a unique maximal local solution X(t)on $t \in [-\tau, \bar{\tau}_e)$ (see, e.g., [5, Theorem 7.12 on page 278]), where $\bar{\tau}_e$ is the explosion time. Defining $Z(t) = X(t) - \Lambda(X(t - \delta_1(t)), r(t), t)$, it is easy to show that $|Z(0)| \leq ||\xi|| + |\Lambda(\xi, r(0), 0)| \leq (1 + \kappa)||\xi||$. Let $k_0 > 0$ be a sufficiently large integer such that $||\xi|| < k_0$. For each integer $k > k_0$, we define the stopping time $\sigma_k = \inf\{t \in [0, \bar{\tau}_e) : |X(t)| \geq k\}$ and $\inf \emptyset = \infty$. Clearly, σ_k is increasing as $k \to \infty$, and $\bar{\sigma}_{\infty} = \lim_{k \to \infty} \sigma_k \leq \bar{\tau}_e$. Hence, the assertion (i) will follow if we can show that $\bar{\sigma}_{\infty} = \infty$ a.s.

By the generalized Itô formula (see, e.g., [5, Theorem 1.45 on page 48]) and Assumption 3, we obtain

$$EV(Z(t \wedge \sigma_k), r(t \wedge \sigma_k), t \wedge \sigma_k)$$

$$= V(Z(0)) + E \int_0^{t \wedge \sigma_k} LV(X(s), X(s - \delta_1(s)), \cdots, X(s - \delta_m(s)), r(s), s) ds$$

$$\leqslant V(Z(0)) + a_1 t - a_2 E \int_0^{t \wedge \sigma_k} U_2(X(s), s) ds$$

$$+ \sum_{l=1}^m c_l (1 - \bar{\delta}_l) E \int_0^{t \wedge \sigma_k} U_2(X(s - \delta_l(s)), s - \delta_l(s)) ds, \qquad (11)$$

but

$$\int_{0}^{t \wedge \sigma_{k}} U_{2}(X(s - \delta_{l}(s)), s - \delta_{l}(s)) ds \leqslant \frac{1}{1 - \bar{\delta}_{l}} \int_{-\tau_{l}}^{0} U_{2}(X(s), s) ds + \frac{1}{1 - \bar{\delta}_{l}} \int_{0}^{t \wedge \sigma_{k}} U_{2}(X(s), s) ds.$$

Thus, we have

$$EV(Z(t \wedge \sigma_k), r(t \wedge \sigma_k), t \wedge \sigma_k) \leqslant K_1 + a_1 t - (a_2 - \sum_{l=1}^m c_l) E \int_0^{t \wedge \sigma_k} U_2(X(s), s) ds,$$

where $K_1 = V(Z(0)) + \sum_{l=1}^m c_l \int_{-\tau_l}^0 U_2(X(s), s) ds$. Using the hypothesis $a_2 > \sum_{l=1}^m c_l$ and Assumption 3, we have

$$EU_1(Z(t \wedge \sigma_k), t \wedge \sigma_k) \leqslant K_1 + a_1 t.$$

Now, we define $\nu_k = \inf_{|z| \ge (1-\kappa)k, t \ge 0} U_1(z, t)$. Then, by (3), we have

$$\begin{aligned} |X(\sigma_k) - \Lambda(X(\sigma_k - \delta_1(\sigma_k)), r(\sigma_k), \sigma_k)| I_{\{\sigma_k \leq t\}} \ge (k - |\Lambda(X(\sigma_k - \delta_1(\sigma_k)), r(\sigma_k), \sigma_k)|) I_{\{\sigma_k \leq t\}} \\ \ge (k - \kappa |X(\sigma_k - \delta_1(\sigma_k))|) I_{\{\sigma_k \leq t\}} \ge (1 - \kappa) k I_{\{\sigma_k \leq t\}}. \end{aligned}$$

By the definition of $U_1(z,t)$ and σ_k , we can obtain

$$K_1 + a_1 t \ge E[U_1(Z(t \wedge \sigma_k), t \wedge \sigma_k)I_{\{\sigma_k \leqslant t\}}]$$

$$\ge E[\inf_{|z| \ge (1-\kappa)k, t \ge 0} U_1(z, t)I_{\{\sigma_k \leqslant t\}}] = \nu_k P\{\sigma_k \leqslant t\}.$$

Noting that $\nu_k \to \infty$ as $k \to \infty$. Then, letting $k \to \infty$ in the last inequality, we have that $P\{\bar{\sigma}_{\infty} \leq t\} = 0$, which implies $\bar{\sigma}_{\infty} > t$ a.s. Also, letting $t \to \infty$, we get that $\bar{\sigma}_{\infty} = \infty$ a.s., which implies the assertion (i).

We now show the assertion (ii). From (11), it follows that

$$(a_2 - \sum_{l=1}^m c_l) E \int_0^{t \wedge \sigma_k} U_2(X(s), s) ds \leqslant K_1 + a_1 t.$$

Dividing both sides of the last inequality by $a_2 - \sum_{l=1}^{m} c_l$, we then have

$$E \int_0^{t \wedge \sigma_k} U_2(X(s), s) ds \leqslant \frac{K_1}{a_2 - \sum_{l=1}^m c_l} + \frac{a_1 t}{a_2 - \sum_{l=1}^m c_l}.$$

Letting $k \to \infty$ and using the well-known Fubini theorem, we obtain

$$\int_{0}^{t} EU_{2}(X(s), s) ds \leqslant \frac{K_{1}}{a_{2} - \sum_{l=1}^{m} c_{l}} + \frac{a_{1}t}{a_{2} - \sum_{l=1}^{m} c_{l}}.$$
(12)

Dividing both sides of inequality (12) by t and letting $t \to \infty$, we obtain (10). Thus, the proof is complete. \Box

Next, we establish the criteria for the stability of the solution obtained in Theorem 1.

Theorem 2. Suppose Assumptions 1, 2 and 3 hold, then for any given initial data (2), the unique global solution to equation (1) has the property that

$$\limsup_{t \to \infty} EU_1(X(t) - \Lambda(X(t - \delta_1(t)), r(t), t), t) < \frac{a_1}{\varepsilon},$$
(13)

where $0 < \varepsilon < 1$ is sufficiently small such that

$$a_2 - \varepsilon C_{\tau_1} - \sum_{l=1}^m c_l e^{\varepsilon \tau_l} > 0, \tag{14}$$

where $C_{\tau_1} = \max\{\frac{\kappa e^{\varepsilon \tau_1}}{1-\overline{\delta_1}} + (1-\kappa)^{1-\beta_h}, \frac{e^{\varepsilon \tau_1}}{1-\overline{\delta_1}} + 1\}$. Moreover, if $a_1 = 0$, then the solution satisfies

$$\limsup_{t \to \infty} \frac{\log U_1(X(t) - \Lambda(X(t - \delta_1(t)), r(t), t), t)}{t} \leqslant -\varepsilon \quad a.s,$$
(15)

and

$$\int_0^\infty U_2(X(t), t)dt < \infty \quad a.s.$$
(16)

Proof: Applying the generalized Itô formula to $e^{\varepsilon(t\wedge\sigma_k)}V(Z(t\wedge\sigma_k), r(t\wedge\sigma_k), t\wedge\sigma_k)$, we obtain

$$Ee^{\varepsilon(t\wedge\sigma_k)}V(Z(t\wedge\sigma_k), r(t\wedge\sigma_k), t\wedge\sigma_k) = V(Z(0), r(0), 0) + E\int_0^{t\wedge\sigma_k} \varepsilon e^{\varepsilon s}V(Z(s), r(s), s)ds + E\int_0^{t\wedge\sigma_k} e^{\varepsilon s}LV(Z(s), X(s-\delta_1(s)), \cdots, X(s-\delta_m(s)), r(s), s)ds.$$

Also, from Assumption 3, we have

$$Ee^{\varepsilon(t\wedge\sigma_k)}U_1(Z(t\wedge\sigma_k)) \leqslant V(Z(0), r_0, 0) + \varepsilon E \int_0^{t\wedge\sigma_k} e^{\varepsilon s}U_2(Z(s), s)ds + \frac{a_1}{\varepsilon}e^{\varepsilon t} - a_2E \int_0^{t\wedge\sigma_k} e^{\varepsilon s}U_2(X(s), s)ds + \sum_{l=1}^m c_l(1-\bar{\delta}_l)E \int_0^{t\wedge\sigma_k} e^{\varepsilon s}U_2(X(s-\delta_l(s)), s-\delta_l(s))ds$$

Noting that

$$\begin{split} &\int_{0}^{t\wedge\sigma_{k}}e^{\varepsilon s}U_{2}(X(s-\delta_{l}(s)),s-\delta_{l}(s))ds \leqslant e^{\varepsilon\tau_{l}}\int_{0}^{t\wedge\sigma_{k}}e^{\varepsilon(s-\delta_{l}(s))}U_{2}(X(s-\delta_{l}(s)),s-\delta_{l}(s))ds \\ &\leqslant \frac{e^{\varepsilon\tau_{l}}}{1-\bar{\delta}_{l}}\int_{-\tau_{l}}^{0}U_{2}(X(s),s)ds + \frac{e^{\varepsilon\tau_{l}}}{1-\bar{\delta}_{l}}\int_{0}^{t\wedge\sigma_{k}}e^{\varepsilon s}U_{2}(X(s),s)ds, \end{split}$$

and by Lemma 1, we obtain

$$Ee^{\varepsilon(t\wedge\sigma_k)}U_1(Z(t\wedge\sigma_k),(t\wedge\sigma_k)) \leqslant K_2 + \frac{a_1}{\varepsilon}e^{\varepsilon t} + \varepsilon C_{\tau_1}E\int_0^{t\wedge\sigma_k}e^{\varepsilon s}U_2(X(s),s)ds - a_2E\int_0^{t\wedge\sigma_k}e^{\varepsilon s}U_2(X(s),s)ds + \sum_{j=1}^m c_le^{\varepsilon\tau_l}E\int_0^{t\wedge\sigma_k}e^{\varepsilon s}U_2(X(s),s)ds,$$

where $K_2 = V(Z(0), r_0, 0) + \frac{\varepsilon e^{\varepsilon \tau_1}}{1-\delta} \int_{-\tau_1}^0 U_2(\xi(s), s) ds + \sum_{l=1}^m c_l e^{\varepsilon \tau_l} \int_{-\tau_l}^0 U_2(\xi(s), s) ds$. By condition (14) and letting $k \to \infty$, we have

$$Ee^{\varepsilon t}U_1(Z(t),t) \leqslant K_2 + \frac{a_1}{\varepsilon}e^{\varepsilon t},$$
(17)

which shows that

$$\limsup_{t \to \infty} EU_1(X(t) - \Lambda(X(t - \delta_1(t)), r(t), t), t) < \frac{a_1}{\varepsilon}$$

and

$$\limsup_{0 \le t < \infty} EU_1(X(t) - \Lambda(X(t - \delta_1(t)), r(t), t), t) < \infty.$$

If $a_1 = 0$, (17) yields

$$Ee^{\varepsilon t}U_1(Z(t),t) \leqslant K_2, \tag{18}$$

which implies that

$$\limsup_{t \to \infty} \frac{\log EU_1(X(t) - \Lambda(X(t - \delta_1(t)), r(t), t), t)}{t} \leqslant -\varepsilon.$$

Moreover, if $a_1 = 0$, from (12) we can then obtain that

$$\int_0^t EU_2(X(s), s) ds \leqslant \frac{K_1}{a_2 - \sum_{l=1}^m c_l}.$$

By letting $t \to \infty$ in the last inequality, we obtain

$$\int_{0}^{\infty} EU_{2}(X(s), s)ds \leqslant \frac{K_{1}}{a_{2} - \sum_{l=1}^{m} c_{l}}.$$
(19)

Furthermore, using the well-known Fubini theorem, we have

$$E\int_0^\infty U_2(X(s),s)ds \leqslant \frac{K_1}{a_2 - \sum_{l=1}^m c_l},$$

which implies (16). Finally, we show that (15) holds. By the generalized Itô formula (see, e.g., [5, Theorem 1.45 on page 48]), we have that for any $t \ge 0$,

$$e^{\varepsilon t}V(Z(t), r(t), t) = V(Z(0), r_0, 0) + \int_0^t \varepsilon e^{\varepsilon s} V(Z(s), r(s), s) ds + \int_0^t e^{\varepsilon s} LV(Z(s), X(s - \delta_1(s)), \cdots, X(s - \delta_m(s)), r(s), s) ds + M(t),$$

where M(t) is a local martingale with the initial value M(0) = 0. For $a_1 = 0$, by the same argument as before, we obtain

$$e^{\varepsilon t}U_1(Z(t),t) \leq K_2 + M(t).$$

Using the nonnegative semimartingale convergence theorem (see, e.g., [8, Theorem 1.3.9 on page 14]), we immediately obtain that

$$\limsup_{t \to \infty} e^{\varepsilon t} U_1(Z(t), t) < \infty \quad \text{a.s.}$$

Therefore, there exists a finite positive random variable η such that

$$\sup_{0 \leqslant t < \infty} e^{\varepsilon t} U_1(Z(t), t) < \varsigma \quad \text{a.s,}$$
⁽²⁰⁾

which implies that

$$\limsup_{t \to \infty} \frac{\log U_1(Z(t), t)}{t} < -\varepsilon \quad \text{a.s.}$$

Hence, the assertion (15) can be obtained. Thus, the proof is complete. \Box

Remark 1. It is important to note that Theorems 1 and 2 are not only applicable in handling NSDDEs that have different parameters in different modes, but can also be applied to NSDDEs that have different structures in different modes. This will be illustrated in Examples 1 and 2.

Remark 2. We also remark that Theorems 1 and 2 are extendable to more general class of equations with neutral parts that include more than one delay.

Corollary 1. Suppose all the conditions of Theorem 2 hold. If there is a pair of positive constants λ and $p \ge 1$ such that

$$\lambda |x|^p \leqslant U_1(x,t), \quad (x,t) \in \mathbb{R}^d \times \mathbb{R}_+, \tag{21}$$

then the solution satisfies

$$\limsup_{t \to \infty} E|X(t)|^p < \infty.$$

Moreover, if $a_1 = 0$ and $\kappa_1 e^{\varepsilon \tau_1} < 1$, then we have

$$\int_0^\infty E|X(t)|^p dt < \infty,$$
(22)

$$\limsup_{t \to \infty} \frac{\log(E|X(t)|^p)}{t} < -\varepsilon$$
(23)

and

$$\limsup_{t \to \infty} \frac{\log |X(t)|}{t} < -\frac{\varepsilon}{p} \quad a.s.$$
(24)

Proof: The proof is similar to the proof of (6). We have that for any $t > \tau$,

$$\sup_{0 \leqslant s \leqslant t} E|X(s)|^{p} \leqslant \sup_{0 \leqslant s \leqslant t} (1-\kappa_{1})^{1-p} E|Z(s)|^{p} + \sup_{0 \leqslant s \leqslant t} \kappa_{1} E|X(s-\delta_{1}(s))|^{p}$$
$$\leqslant \sup_{0 \leqslant s \leqslant t} (1-\kappa_{1})^{1-p} E|Z(s)|^{p} + \kappa_{1} \|\xi\|^{p} + \sup_{0 \leqslant s \leqslant t} \kappa_{1} E|X(s)|^{p}.$$
(25)

Thus, we obtain

$$(1 - \kappa_1) \sup_{0 \le s \le t} E|X(s)|^p \le (1 - \kappa_1)^{1-p} \sup_{0 \le s \le t} E|Z(s)|^p + \kappa_1 ||\xi||^p$$

Letting $t \to \infty$, we have

$$(1 - \kappa_1) \sup_{0 \leqslant s < \infty} E|X(s)|^p \leqslant (1 - \kappa_1)^{1-p} \sup_{0 \leqslant s < \infty} E|Z(s)|^p + \kappa_1 \|\xi\|^p,$$
(26)

which, with (13) and (21), show that

$$\limsup_{t \to \infty} E|X(t)|^p \leqslant \frac{1}{\lambda(1-\kappa_1)^p} \limsup_{t \to \infty} EU_1(Z(t),t) + \frac{\kappa_1}{\lambda(1-\kappa_1)} \|\xi\|^p < \infty.$$

For $a_1 = 0$, using (9), (19) and (21). Therefore, we obtain

$$\int_0^\infty E|X(t)|^p dt \leqslant \frac{1}{\lambda} \int_0^\infty EU_1(X(t), t) dt \leqslant \frac{1}{\lambda} \int_0^\infty EU_1(X(t), t) dt \leqslant \frac{K_1}{\lambda(a_2 - \sum_{l=1}^m c_l)} < \infty.$$

Recalling (18) and (25) we see that for any t > 0,

$$\sup_{0\leqslant s\leqslant t} e^{\varepsilon s} E|X(s)|^{p} \leqslant (1-\kappa_{1})^{1-p} \sup_{0\leqslant s\leqslant t} e^{\varepsilon s} E|Z(s)|^{p} + \kappa_{1} \sup_{0\leqslant s\leqslant t} e^{\varepsilon s} E|X(s-\delta_{1}(s))|^{p}$$
$$\leqslant \frac{K_{2}(1-\kappa_{1})^{1-p}}{\lambda} + e^{\varepsilon\tau_{1}}\kappa_{1}\|\xi\|^{p} + e^{\varepsilon\tau_{1}}\kappa_{1} \sup_{0\leqslant s\leqslant t} e^{\varepsilon s} E|X(s)|^{p},$$

which implies

$$\sup_{0\leqslant s\leqslant t} e^{\varepsilon s} E|X(s)|^p \leqslant \frac{K_2(1-\kappa_1)^{1-p}}{\lambda(1-\kappa_1 e^{\varepsilon\tau_1})} + \frac{e^{\varepsilon\tau_1}\kappa_1}{1-\kappa_1 e^{\varepsilon\tau_1}} \|\xi\|^p$$

By letting $t \to \infty$, then the assertion (23) is obtained. Employing a similar argument as (26), we have

$$(1 - \kappa_1) \sup_{0 \le t < \infty} |X(t)|^p \le (1 - \kappa_1)^{1-p} \sup_{0 \le t < \infty} |Z(t)|^p + \kappa_1 ||\xi||^p.$$

By inequalities (20) and (21), we have

$$\sup_{0 \le t < \infty} |X(t)|^p \le \frac{(1 - \kappa_1)^{1-p}}{\lambda(1 - \kappa_1)} \sup_{0 \le t < \infty} U_1(Z(t), t) + \frac{\kappa_1}{1 - \kappa_1} \|\xi\|^p < \infty \quad a.s.$$

From inequality (20), for any $t > \tau$, we have that

$$\begin{split} \sup_{0\leqslant s\leqslant t} e^{\varepsilon s} |X(s)|^p &\leqslant (1-\kappa_1)^{1-p} \sup_{0\leqslant s\leqslant t} e^{\varepsilon s} |Z(s)|^p + \kappa_1 e^{\varepsilon s} \sup_{0\leqslant s\leqslant t} |X(s-\delta_1(s))|^p \\ &\leqslant \frac{(1-\kappa_1)^{1-p}}{\lambda} \sup_{0\leqslant s<\infty} e^{\varepsilon t} U_1(Z(s),s) + e^{\varepsilon \tau_1} \kappa_1 \|\xi\|^p + e^{\varepsilon \tau_1} \kappa_1 \sup_{0\leqslant s<\infty} e^{\varepsilon s} |X(s)|^p \\ &\leqslant \frac{(1-\kappa_1)^{1-p}}{\lambda} \varsigma + e^{\varepsilon \tau_1} \kappa_1 \|\xi\|^p + e^{\varepsilon \tau_1} \kappa_1 \sup_{0\leqslant s\leqslant t} e^{\varepsilon s} |X(s)|^p, \end{split}$$

which implies

$$\sup_{0\leqslant s\leqslant t} e^{\varepsilon s} |X(s)|^p \leqslant \frac{\zeta(1-\kappa_1)^{1-p}}{\lambda(1-\kappa_1 e^{\varepsilon\tau_1})} + \frac{e^{\varepsilon\tau_1}\kappa_1}{1-\kappa_1 e^{\varepsilon\tau_1}} \|\xi\|^p < \infty \quad a.s.$$

Letting $t \to \infty$ in the last inequality yields the assertion (24). Thus, the proof is complete. \Box

The following criterion is very convenient for the mean square exponential stability since the main condition is explicitly related to the coefficients f and g. Before we give the criterion, it is necessary to make some assumptions

Assumption 4. We assume that there is a constant q > 2. Assume that there are $\alpha_{i1} \in R$, and $\alpha_{i2l}, \beta_{i3}, \beta_{i4l} \in R_+, l = 1, \dots, m$ such that

$$(x - \Lambda(y_1, i, t))^T f(x, y_1, \cdots, y_m, i, t) + \frac{1}{2} |g(x, y_1, \cdots, y_m, i, t)|^2$$

$$\leqslant \beta_{i1} |x|^2 + \sum_{l=1}^m \beta_{i2l} |y_l|^2 - \beta_{i3} |x|^q + \sum_{l=1}^m \beta_{i4l} |y_l|^q,$$

for each $i \in S$.

Assumption 5. We assume

$$\mathcal{A} = -\text{diag}(2\beta_{11}, \cdots, 2\beta_{N1}) - \Gamma - \hat{\Gamma}$$

is a nonsingular M-matrix, where $\hat{\Gamma} = (|\gamma_{ij}|\kappa_i)_{N \times N}$. Set

$$(\lambda_1, \cdots, \lambda_N)^T = \mathcal{A}^{-1}(1, \cdots, 1)^T,$$

then $\lambda_i > 0$ for all $i \in S$.

Theorem 3. Let Assumptions 4 and 5 hold, and let $b_1 = \min_{i \in S} \lambda_i, b_2 = \max_{i \in S} \lambda_i, \theta_{21} = \max_{i \in S} \{2\lambda_i \beta_{i21} + \sum_{j \in S, j \neq i} \kappa_i^2 \gamma_{ij} \lambda_j\}, \theta_{2l} = \max_{i \in S} \{2\lambda_i \beta_{i2l}\}, \text{ where } l = 2, \cdots, m, \theta_3 = \min_{i \in S} \{2\lambda_i \beta_{i3}\}, \theta_{4l} = \max_{i \in S} \{2\lambda_i \beta_{i4l}\}, \text{ where } l = 1, \cdots, m, \text{ and } c_l = \max \{\frac{\theta_{2l}}{1 - \delta_l}, \frac{\theta_{4l}}{\theta_3(1 - \delta_l)}\}, \text{ where } l = 1, \cdots, m.$

$$1 > \sum_{l=1}^{m} c_l,$$
 (27)

then we have that

$$\limsup_{t \to \infty} \frac{\log(E|X(t)|^2)}{t} < -\varepsilon$$
(28)

and

$$\limsup_{t \to \infty} \frac{\log |X(t)|}{t} < -\frac{\varepsilon}{2} \quad a.s.$$
⁽²⁹⁾

Proof: Let $V(x, i, t) = \lambda_i |x|^2$, $U_1(x, t) = b_1 |x|^2$, $U_2(x, t) = b_2 |x|^2 + b_2 \theta_3 |x|^q$. Clearly,

$$U_1(x,t) \leqslant V(x,i,t) \leqslant U_2(x,t).$$

Now, we compute $LV(z, y_1, \cdots, y_m, i, t)$. For any $i \in S$,

$$\begin{split} LV(z,y_1,\cdots,y_m,t,i) &= 2\lambda_i \Big[(x-\Lambda(y_1,i,t))^T f(x,y_1,\cdots,y_m,i,t) + \frac{1}{2} |g(x,y_1,\cdots,y_m,i,t)|^2 | \Big] \\ &+ \sum_{j \in S} \lambda_j \gamma_{ij} (x-\Lambda(y_1,i,t))^T (x-\Lambda(y_1,i,t)) \\ &\leqslant 2\lambda_i \beta_{i1} |x|^2 + 2\lambda_i \sum_{l=1}^m \beta_{i2l} |y_l|^2 - 2\lambda_i \beta_{i3} |x|^q + 2\lambda_i \sum_{j=1}^m \beta_{i4l} |y_l|^q \\ &+ \sum_{j \in S} \lambda_j \gamma_{ij} |x|^2 - 2 \sum_{j \in S} \lambda_j \gamma_{ij} x^T \Lambda(y_1,i,t) + \sum_{j \in S} \lambda_j \gamma_{ij} |\Lambda(y_1,i,t)|^2 \\ &\leqslant \Big[2\lambda_i \ \beta_{i1} + \sum_{j \in S} \lambda_j \gamma_{ij} + \sum_{j \in S} \kappa_i \lambda_j |\gamma_{ij}| \Big] |x|^2 + 2\lambda_i \sum_{l=1}^m \beta_{i2l} |y_l|^2 \\ &+ \Big[\sum_{j \in S} \kappa_i |\gamma_{ij}| \lambda_j + \sum_{j \in S, j \neq i} \kappa_i^2 \gamma_{ij} \lambda_j \Big] |y_1|^2 - 2\lambda_i \beta_{i3} |x|^q + 2\lambda_i \sum_{l=1}^m \beta_{i4l} |y_l|^q. \end{split}$$

Furthermore, by definitions of $\theta_{21}, \theta_{2l}, \theta_3$ and θ_{4l} , we have

$$LV(x - \Lambda(y_1, i, t), y_1, \cdots, y_m, t, i) \leq -|x|^2 + \sum_{l=1}^m \theta_{2l} |y_l|^2 - \theta_3 |x|^q + \sum_{l=1}^m \theta_{4l} |y_l|^q$$
$$\leq -\frac{1}{b_2} U_2(x, t) + \frac{1}{b_2} \sum_{l=1}^m c_l (1 - \bar{\delta}_l) U_2(y_l, t - \delta_l(t)).$$

Hence, the assertions (28) and (29) follow from Corollary 1. \Box

4 Examples

In this section, we will use three examples to illustrate our theorems. Although these examples are scalar highly nonlinear hybrid NSDDEs with constant delays, they are fully covered our theorems. **Example 1.** Consider the following scalar hybrid NSDDE

$$d[X(t) - \Lambda(X(t - \tau_1), r(t), t)] = f(X(t), X(t - \tau_1), X(t - \tau_2), r(t), t)dt + g(X(t - \tau_2), r(t), t)dB(t),$$
(30)

where r(t) is a Markov chain on the state space $S = \{1, 2\}$ with its generator

$$\Gamma = \begin{pmatrix} -1 & 1 \\ 2 & -2 \end{pmatrix},$$

and the coefficients are defined as follows:

$$\begin{split} f(x,y_1,y_2,1,t) &= y_1 + y_2^3 - 6x - 6x^3, \quad f(x,y_1,y_2,2,t) = y_1 + y_2^3 - 3x - 4x^3, \\ g(y_2,1,t) &= g(y_2,2,t) = 0.5y_2^2, \quad \Lambda(y_1,1,t) = \Lambda(y_1,2,t) = 0.1y_1. \end{split}$$

In mode 1, the system is described by the NSDDE

$$d[X(t) - 0.1X(t - \tau_1)] = [X(t - \tau_1) + X^3(t - \tau_2) - 6X(t) - 6X^3(t)]dt + 0.5X^2(t - \tau_2)dB(t),$$

while in mode 2 it is described by

$$d[X(t) - 0.1X(t - \tau_1)] = [X(t - \tau_1) + X^3(t - \tau_2) - 3X(t) - 4X^3(t)]dt + 0.5X^2(t - \tau_2)dB(t).$$

It is easy to see that the two modes have the same structure but different parameters, which means that the system only experiences abrupt changes in its parameters.

Before applying our theorem, we set $\tau_1 = 2$ and $\tau = \tau_2 = 3$. Let

$$V(x, i, t) = \begin{cases} x^2 + x^4 & \text{if } i = 1, \\ 2x^2 + 2x^4 & \text{if } i = 2. \end{cases}$$

Then, we obtain

$$LV(x - \Lambda(y_1, 1, t), y_1, y_2, 1, t) = (2(x - 0.1y_1) + 4(x - 0.1y_1)^3)(y_1 + y_2^3 - 6x - 6x^3) + (0.25 + 1.25(x - 0.1y_1)^2)y_2^4 + (x - 0.1y_1)^2 + (x - 0.1y_1)^4$$

and

$$LV(x - \Lambda(y_1, 2, t), y_1, y_2, 2, t) = (4(x - 0.1y_1) + 8(x - 0.1y_1)^3)(y_1 + y_2^3 - 3x - 4x^3) + (0.5 + 3(x - 0.1y_1)^2)y_2^4 - 2(x - 0.1y_1)^2 - 2(x - 0.1y_1)^4.$$

Applying the inequalities $(a + b)^p \leq (1 + \rho)^{p-1}(a^p + \rho^{1-p}b^p)$, here setting $\rho = \kappa/(1 - \kappa) = 1/9$, and $a^\beta b^{1-\beta} \leq \beta a + (1 - \beta)b$, we obtain

$$\begin{aligned} 4(x-0.1y_1)^3(y_1+y_2^3) &\leqslant 4.94|x|^3|y_1|+0.4y_1^4+4.94|x|^3|y_2|^3+0.4|y_1|^3|y_2|^3\\ &\leqslant 3.72x^4+1.64y_1^4+2.47x^6+0.2y_1^6+2.67y_2^6, \end{aligned}$$

and

$$(x - 0.1y_1)^2 \leq 1.1x^2 + 0.11y_1^2, \quad (x - 0.1y_1)^4 \leq 1.38x^4 + 0.1y_1^4$$

and $(0.25 + 1.5(x - 0.1y_1)^2)y_2^4 \leq 0.56x^6 + 0.25y_2^4 + 0.05y_1^6 + 1.44y_2^6$

By the well-known Young inequality, we have

$$2(x-0.1y_1)(y_1+y_2^3-6x-6x^3) \leqslant -10.4x^2+1.4y_1^2-10.6x^4+0.35y_1^4+1.65y_2^4,$$

$$-24x(x-0.1y_1)^3 \leqslant -18.594x^4 + 1.818y_1^4 \quad \text{and} \quad -24x^3(x-0.1y_1)^3 \leqslant -17.988x^6 + 1.212y_1^6.$$

Hence,

 $LV(x - \Lambda(y_1, 1, t), y_1, y_2, 1, t) \leqslant -14.958x^6 - 24.094x^4 - 9.3x^2 + 1.462y_1^6 + 3.908y_1^4 + 1.51y_1^2 + 3.89y_2^6 + 1.9y_2^4.$ Similarly,

$$LV(x - \Lambda(y_1, 2, t), y_1, y_2, 2, t) \leqslant -17.924x^6 - 26.348x^4 - 11.2x^2 + 2.116y_1^6 + 5.8y_1^4 + 2.38y_1^2 + 7.78y_2^6 + 3.8y_2^4 + 2.116y_1^6 + 5.8y_1^4 + 2.38y_1^2 + 7.78y_2^6 + 3.8y_2^4 + 2.116y_1^6 + 5.8y_1^4 + 2.38y_1^2 + 7.78y_2^6 + 3.8y_2^4 + 2.116y_1^6 + 5.8y_1^4 + 2.38y_1^2 + 7.78y_2^6 + 3.8y_2^4 + 2.116y_1^6 + 5.8y_1^4 + 2.38y_1^2 + 7.78y_2^6 + 3.8y_2^4 + 2.116y_1^6 + 5.8y_1^4 + 2.38y_1^2 + 7.78y_2^6 + 3.8y_2^6 +$$

Therefore,

$$\begin{split} LV(x - \Lambda(y_1, i, t), y_1, y_2, i, t) \leqslant &-14.958x^6 - 24.094x^4 - 9.3x^2 + 2.116y_1^6 + 5.68y_1^4 + 2.38y_1^2 + 7.78y_2^6 + 3.8y_2^4 \\ \leqslant &-4.6(3x^6 + 5x^4 + 2x^2) + 1.2(3y_1^6 + 5y_1^4 + 2y_1^2) + 2.6(3y_2^6 + 5y_2^4 + 2y_2^2). \end{split}$$

Letting $U_1(x,t) = x^2 + x^4$ and $U_2(x,t) = 2x^2 + 5x^4 + 3x^6$, we have $U_1(x,t) \leq V(x,i,t) \leq U_2(x,t)$. Thus, we have $a_1 = 0, a_2 = 4.6, c_1 = 1.2, c_2 = 2.6$. By Theorem 2 and Corollary 1, we conclude that the hybrid system (30) is fourth moment exponential stable. This result is also supported by the simulation analysis carried out (see Figure 1 below).

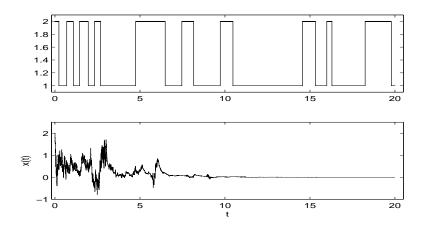

Figure 1: Computer simulation of the stochastic trajectories of the Markov chain and the NSDDE (30).

Example 2. Let r(t) be a Markov chain on the state space $S = \{1, 2\}$ with generator

$$\Gamma = \begin{pmatrix} -1 & 1\\ 10 & -10 \end{pmatrix}.$$

Consider the following scalar hybrid NSDDE

$$d[X(t) - \Lambda(X(t - \tau_1), r(t), t)] = f(X(t), X(t - \tau_1), r(t), t)dt + g(X(t - \tau_2), r(t), t)dB(t),$$
(31)

where $\tau_1 = 1, \tau_2 = 2,$

$$\begin{aligned} f(x, y_1, 1, t) &= y_1 - 4x - 4x^3, \quad f(x, y_1, 2, t) = 0.5x, \quad g(y_2, 1, t) = y_2^2, \\ g(y_2, 2, t) &= 0.5y_2, \quad \Lambda(y_1, 1, t) = \Lambda(y_1, 2, t) = 0.1y_1. \end{aligned}$$

It is clear that the system has different structures in different modes. In mode 1, both f and g are highly nonlinear functions, while in mode 2, f and g are linear functions. This shows that the system experiences abrupt changes in its structure. Next, we will show that our theorem can be applied to systems which have different structures in different modes.

Let

$$V(x, i, t) = \begin{cases} x^2 & \text{if } i = 1, \\ 2x^2 + x^4 & \text{if } i = 2. \end{cases}$$

It is easy to show that

$$LV(x - \Lambda(y_1, 1, t), y_1, y_2, 1, t) \leqslant -5.4x^2 - 6x^4 + 1.3y_1^2 + 0.3y_1^4 + y_2^4,$$

and

$$LV(x - \Lambda(y_1, 2, t), y_1, y_2, 2, t) \leqslant -6.9x^2 - 3x^4 + y_1^2 + 1.4y_1^4 + 0.5y_2^2 + y_2^4.$$

Hence, we have

$$LV(x - \Lambda(y_1, i, t), y_1, y_2, i, t) \leq -5.4x^2 - 3x^4 + 1.3y_1^2 + 1.4y_1^4 + 0.5y_2^2 + y_2^4$$
$$\leq -2.7(2x^2 + x^4) + 1.4(2y_1^2 + y_1^4) + (2y_2^2 + y_2^4).$$

If we set $U_1(x,t) = x^2$ and $U_2(x,t) = 2x^2 + x^4$, then we have $U_1(x,t) \leq V(x,i,t) \leq U_2(x,t)$, $a_1 = 0, a_2 = 2.7, c_1 = 1.4$ and $c_2 = 1$. By Theorem 2 and Corollary 1, we conclude that the NSDDE (31) is almost sure exponential stable. The sample paths of the Markov chain and the solution of the NSDDE (31) are plotted in Figure 2.

Example 3. In this example, we use the method of M-matrix to analysis the stability of NSDDEs. Let r(t) be a Markov chain on the state space $S = \{1, 2\}$ with its generator as

$$\Gamma = \begin{pmatrix} -1 & 1\\ 10 & -10 \end{pmatrix}.$$

Consider the following scalar hybrid NSDDE

$$d[X(t) - \Lambda(X(t - \tau_1), r(t), t)] = f(X(t), X(t - \tau_1), X(t - \tau_2), r(t), t)dt + g(X(t - \tau_2), r(t), t)dB(t),$$
(32)

on $t \ge 0$, where

$$\tau_1 = 1, \quad \tau_2 = 2, \quad f(x, y_1, y_2, 1, t) = y_1 + y_2^3 - 6x - 6x^3, \quad f(x, y_1, y_2, 2, t) = 0.2y_1 + \frac{1}{2}y_2^3 - 4x^3,$$

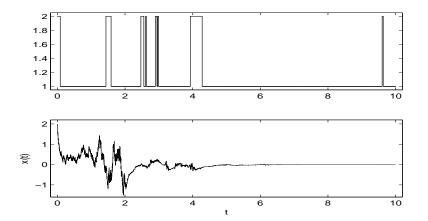

Figure 2: Computer simulation of the sample paths of the Markov chain and the NSDDE (31).

 $g(y_2, 1, t) = y_2, \quad g(y_2, 2, t) = 0.5y_2, \quad \Lambda(y_1, 1, t) = \Lambda(y_1, 2, t) = 0.1y_1.$

We estimate as follows:

$$(x - \Lambda(y_1, 1, t))^T f(x, y_1, y_2, 1, t) + \frac{1}{2} |g(x, y_2, 1, t)|^2 = (x - 0.1y_1)(y_1 + y_2^3 - 6x - 6x^3) + \frac{1}{2}y_2^2 \\ \leqslant -5.2x^2 + 0.7y_1^2 + 0.5y_2^2 - 5.35x^4 + 0.225y_1^4 + 0.825y_2^4,$$

and

$$(x - \Lambda(y_1, 2, t))^T f(x, y_1, y_2, 2, t) + \frac{1}{2} |g(x, y_2, 2, t)|^2 = (x - 0.1y_1)(0.2y_1 + \frac{1}{2}y_2^3 - 4x^3) + \frac{1}{2}y_2^2 \le 0.1x^2 + 0.08y_1^2 + 0.125y_2^2 - 3.575x^4 + 0.1125y_1^4 + 0.4125y_2^4.$$

Thus, we have

$$\begin{split} \beta_{11} &= -5.2, \ \beta_{21} = 0.1, \ \beta_{121} = 0.7, \ \beta_{122} = 0.5, \ \beta_{221} = 0.08, \ \beta_{222} = 0.125, \\ \beta_{13} &= 5.35, \ \beta_{23} = 3.45, \ \beta_{141} = 0.225, \ \beta_{142} = 0.825, \ \beta_{241} = 0.1125, \ \beta_{242} = 0.4125. \end{split}$$

By Assumption 5, we derive that

$$\mathcal{A} = \begin{pmatrix} 11.3 & -1.1 \\ -11 & 8.8 \end{pmatrix}, \quad \mathcal{A}^{-1} = \begin{pmatrix} 0.1008 & 0.0126 \\ 0.1259 & 0.1294 \end{pmatrix}, \quad \lambda_1 = 0.1234 \quad \text{and} \quad \lambda_2 = 0.2553.$$

Thus, by Theorem 3 we have the following computed:

$$b_1 = 0.1234, \ b_2 = 0.2553, \ \theta_{21} = 0.432, \ \theta_{22} = 0.1234, \ \theta_3 = 1.3203, \\ \theta_{41} = 0.0556, \ \theta_{42} = 0.2107, \ c_1 = 0.432, \ c_2 = 0.1596.$$

Hence, inequality (27) holds. Consequently, by Theorem 3, we conclude that the NSDDE (32) is stable, although the second subsystem is unstable. Figure 3 illustrates the sample paths of the Markov chain and the NSDDE (32).

5 Conclusion

In this study, we investigated boundedness and stability of highly nonlinear hybrid NSDDEs with multiple delays without assuming linear growth condition. We also introduce a general Lyapunov function to over come the difficulties in handling nonlinear growth conditions. Furthermore, the method of M-matrix was utilized to analyze mean square exponential stability of NSDDEs. Our results can be applied to a larger class of hybrid NSDDEs which may have different structures or parameters in different modes. We have also presented three examples to demonstrate the applicability of our theorems.
