Two isostructural polymetallic complexes [Mn$_{5}^{III}$(μ$_{3}$-O)$_{2}$(CH$_{3}$COO)$_{4}$]$_{4}$– and [Mn$_{5}^{III}$(μ$_{3}$-O)$_{2}$(CH$_{3}$COO)$_{4}$]$_{4}$ have been synthesised by using two Schiff base ligands derived from 3,5-diamino-1,2,4-triazole, following two different preparative routes, either using the pre-formed ligand (for L1) or via a metal-mediated template synthesis (for L2). The {Mn$_{5}^{III}$} structure is unusual, being based on two corner-sharing perpendicular (Mn$_{3}$) triangles forming a twisted bow-tie. The magnetic studies reveal antiferromagnetic coupling between Mn(III) ions while electrochemical experiments are consistent with a quasi-reversible Mn(II) ↔ Mn(IV) redox process at the central manganese ion.

Introduction

Manganese is an excellent candidate for the synthesis and study of new molecular magnetic materials a, b, c, d, e, f, g, h, i, j, k, l, m, n, o, p, q, r, s, t, u, v, w, x, y, z with a range of easily accessible oxidation states from Mn(II) to Mn(IV). a, b Mn(II) ions are employed in the design of nanomagnets due to the characteristic magnetic anisotropy (D), a, b, c, d, e, f, g, h, i, j, k, l, m, n, o, p, q, r, s, t, u, v, w, x, y, z whereas Mn(III) ions are used in molecular magnetic refrigerants, considering the relatively large number of unpaired electrons and the typical isotropic octahedral environment. a, b, c, d, e, f, g, h, i, j, k, l, m, n, o, p, q, r, s, t, u, v, w, x, y, z In addition, the stability of these multiple oxidation states provides an opportunity to explore the redox properties in polymetallic Mn complexes. a, b, c, d, e, f, g, h, i, j, k, l, m, n, o, p, q, r, s, t, u, v, w, x, y, z The synthetic routes to these complexes are mainly serendipitous self-assembly, which commonly uses flexible ligands, and/or rational design, which involves more rigid, polycrystalline ligands. a, b, c, d, e, f, g, h, i, j, k, l, m, n, o, p, q, r, s, t, u, v, w, x, y, z One of the advantages of the second approach is the degree of control in the assembly of the metal ions through the pre-design of the ligand. Schiff base ligands have been used in this type of strategy, a, b, c, d, e, f, g, h, i, j, k, l, m, n, o, p, q, r, s, t, u, v, w, x, y, z and in some cases, these ligands can provide additional redox properties to complexes as a result of the presence of iminic groups. a, b Importantly, the iminic bonds make the ligand flexible enough to accommodate different coordination environments based on the type and/or valence of the metal ions. Considering these factors, we proposed the use of the 3,5-diamino-1,2,4-triazole derivatives, N-(2-hydroxy-3-methoxybenzylene)-3,5-diamino-1,2,4-triazole (H$_{2}$L1) and N-salicylendioxy-3,5-diamino-1,2,4-triazole (H$_{2}$L2) to direct the synthesis of new polymetallic manganese complexes. Unlike other diamines, 3,5-diamino-1,2,4-triazole derivatives have not been explored in any polymeric manganese complexes. a, b, c, d, e, f, g, h, i, j, k, l, m, n, o, p, q, r, s, t, u, v, w, x, y, z In this work we describe the preparation of two new penta-nuclear Mn(III) compounds, (HNEt$_{3}$)[Mn$_{5}^{III}$(μ$_{3}$-O)$_{2}$(CH$_{3}$COO)$_{4}$]$_{4}$–4CH$_{3}$CN-4H$_{2}$O (1) and (HNEt$_{3}$)[Mn$_{5}^{III}$(μ$_{3}$-O)$_{2}$(CH$_{3}$COO)$_{4}$]$_{4}$–4CH$_{3}$CN-2CH$_{3}$OH (2) and report their structural, magnetic and electrochemical properties.

Experimental section

Materials and physical measurements

All reagents and solvents were obtained from commercial suppliers and used without further purification.

Crystallographic data were collected for 1 and 2 at 100 K using Mo-Kα radiation (λ = 0.71073 Å). For 1 a Bruker APEXII CCD diffractometer with an Oxford Cryosystems n-Helix low-temperature device mounted on a sealed tube generator was used; for 2 a Rigaku AFC12 goniometer equipped with an (HG) Saturn724++ detector mounted on an FR-E+ SuperBright rotating anode generator with HF Varimax optics (100 μm focus). a, b, c, d, e, f, g, h, i, j, k, l, m, n, o, p, q, r, s, t, u, v, w, x, y, z Both structures were solved using SHELXS-25 and refined using...
full-matrix least squares refinement on F² using SHELXL2014. Further details of disorder modelling and hydrogen atom treatment are given in the ESL. The powder X-ray patterns for 1 and 2 were collected on a PANalytical X-Pert MPD, with Cu Kα radiation at ambient temperature over a range of 5° < 2θ < 50° using a step size of 0.0167°. The calculated pattern was generated from Mercury using the cif of the crystal structure at 100 K.

The IR spectra were measured using a FTIR-8400S SHIMADZU IR spectrophotometer. The microanalyses and mass spectrometry analyses were performed by the analytical services of the School of Chemistry at the University of Glasgow. The 1H-NMR spectrum of H₂L1 was obtained using a Bruker AV 400 M MHz. Magnetic measurements of complexes 1 and 2 were carried out on phase-pure (Fig. S4 in the ESI) polycrystalline samples that were lightly powdered and constrained in eicosane, using a Quantum Design MPMS-XL SQUID magnetometer. Data were corrected for the diamagnetic contribution of the sample holder and eicosane by measurements, and for the diamagnetism of the compounds.

Electrochemical measurements were performed on a CH Instruments 760D Electrochemical Workstation using CHI Version 10.03 software. Electrochemical experiments for obtaining the cyclic voltammograms (CVs) were conducted at 298 K using a CH Instruments glassy carbon button working electrode, and Pt mesh counter electrode in a single compartment cell. Bulk electrolys were performed in a similar manner, but using a large surface area reticulated glassy carbon electrode (BASI) as the working electrode. All electrode potentials were referenced to the ferrocene/ferrocenium couple.

Results and discussion

There are very few examples of complexes formed using 1,2,4-triazole derivatives where the magnetic properties have been investigated, these being mainly copper complexes. Surprisingly, there is a lack of magnetic studies performed on such complexes with other 3d ions (vide supra) such as Mn. Furthermore, the only report of the coordination chemistry of L1 and L2 is with oxovanadium(IV). A solution of salicyaldehyde (0.13 mL, 1.25 mmol) was added to a suspension of 3,5-diamino-1,2,4-triazole (0.12 g, 1.25 mmol) in CH₃OH (50 mL). To the resulting pale yellow solution a light brown suspension of Mn(CH₃COO)₂·2H₂O (0.42 g, 1.56 mmol) in CH₃CN (50 mL) was added to give a dark brown suspension. Et₃N (0.35 ml, 2.50 mmol) and Na(CH₃COO) (0.10 g, 1.25 mmol) were consecutively added, giving a dark brown suspension. The suspension was heated at 90 °C for one and a half hours. Dark brown plate-like single crystals suitable for X-ray diffraction appeared after 3 days through slow evaporation of the reaction solution. Yield 31% (131 mg). IR (ν in cm⁻¹): 3385 (w), 1584 (s), 1372 [M + H + Na]⁺, 1429 [M + Na]⁺. MS (ESI+, DMF, m/z): 1372 [M + H + Na]⁺.

Synthetic methods

C₁₀H₁₉N₅O₄ (H₂L1). To a suspension of 3,5-diamino-1,2,4-triazole (0.85 g, 8.6 mmol) in CH₃OH (115 mL) o-vanillin (1.31 g, 8.6 mmol) was added. The resultant yellow solution was stirred and refluxed for 5 hours to yield a deep yellow suspension. Once cooled, the final yellow precipitate was collected via filtration, washed with small volumes of MeOH and dried with Et₂O. Yield 83% (1.67 g). 1H-NMR (DMSO-d₆): 3.83 (s; 3H, CH₃), 6.23 (s; 2H, NH₂), 6.91 (t, 1H, Cα-H), 7.14 (d, 1H, Cβ-H), 7.26 (d, 1H, Cγ-H), 9.15 (s; 1H, HC═N), 12.13 (s; 1H, OH), 12.87 (s; 1H, NH). IR (ν in cm⁻¹): 3127 (m), 1651 (s), 1605 (s), 1469 (m) 1256 (s), 785 (s), 735 (s). MS (ESI+, m/z): 256 [C₁₀H₁₉N₂O₄ + Na⁺].

(HNEt₃)[Mn₂(μ-O)₅(CH₂COO)₄(L1)₄]·4CH₃CN·4H₂O (1). Mn(CH₃COO)₂·2H₂O (0.1 g, 0.37 mmol) was added to a pale yellow suspension of H₂L1 (0.07 g, 0.3 mmol) in CH₃CN (20 mL) to give a pale brown suspension. A solution of Et₃N (0.08 mL, 0.6 mmol) was then added drop-wise to give a dark brown suspension. The suspension was then heated to 90 °C for one and a half hours after which the dark brown solution was attained. Dark brown plate-like single crystals suitable for X-ray diffraction were obtained after 4 days through slow evaporation. Yield 48% (53 mg). IR (ν in cm⁻¹): 3385 (w), 1584 (s), 1431 (s), 1250 (s), 1215 (s), 974 (w), 746 (m), 606 (s). Elemental analysis: ([(HNEt₃)[Mn₂(μ-O)₅(CH₂COO)₄(L1)₄]·5H₂O] [%, found: C 39.86, H 4.34, N 17.73; calc.: C 39.10, H 4.44, N 17.73. MS (ESI–, CH₃CN, m/z): 1469 [M‒]. MS (ESI+, DMF, m/z): 1429 [M – OAc + H₂O]⁺.

(HNEt₃)[Mn₂(μ-O)₅(CH₂COO)₄(L2)₄]·CH₃CN·2CH₃OH (2). A solution of salicyaldehyde (0.13 mL, 1.25 mmol) was added to a suspension of 3,5-diamino-1,2,4-triazole (0.12 g, 1.25 mmol) in CH₃OH (50 mL). To the resulting pale yellow solution a light brown suspension of Mn(CH₃COO)₂·2H₂O (0.42 g, 1.56 mmol) in CH₃CN (50 mL) was added to give a dark brown suspension. Et₃N (0.35 ml, 2.50 mmol) and Na(CH₃COO) (0.10 g, 1.25 mmol) were consecutively added, giving a dark brown suspension. The suspension was heated at 90 °C for one and a half hours. Dark brown plate-like single crystals suitable for X-ray diffraction appeared after 3 days through slow evaporation of the reaction solution. Yield 31% (131 mg). IR (ν in cm⁻¹): 3389 (w), 1585 (s), 1441 (m), 1404 (m), 1288 (s), 924 (m), 760 (s), 604 (s). Elemental analysis: ((HNEt₃)[Mn₂(μ-O)₅(CH₂COO)₄(L2)₄]·1.75CH₃OH·5H₂O] [%, found: C 38.78, H 4.37, N 18.29; calc.: C 38.97, H 4.55, N 18.44. MS (ESI+, CH₃CN, m/z): 1372 [M + H + Na]⁺.

(HNEt₃)[Mn₂(μ-O)₅(CH₂COO)₄(L2)₄]·4CH₃CN·4H₂O (1). The synthetic route to H₂L1 was carried out to that previously reported, as we obtained pure H₂L1 straight from the condensation without re-crystallisation (checked by ¹H NMR).

The reaction between H₂L1 and Mn(CH₃COO)₂·4H₂O in the presence of Et₃N allows the assembly of (HNEt₃)[Mn₂(μ-O)₅(CH₂COO)₄(L1)₄]·4CH₃CN·4H₂O (1). An alternative synthetic route to that described for H₂L1 was carried out to obtain H₂L2 (see Fig. 1, left), based on the use of salicylaldehyde...
instead of o-vanillin. The condensation reaction to form the Schiff base was avoided as we were not able to isolate H₂L₂ as a pure product. Instead, a metal mediated template synthesis was used, yielding successfully the isostructural complex [HNEt₃][Mn³⁺][μ₂-O]₂(CH₃COO)₄(L₂)₄·CH₃CN·2CH₃OH (2). Note that our attempts to form coordination complexes using the corresponding di-substituted 1,2,4-triazole ligands proved unsuccessful, and in the case of the reaction with Mn(CH₃COO)₂·4H₂O the di-substituted ligand decomposed through breaking one imine bond to coordinate as H₂L₁ units which share a central Mn(III) ion (Fig. 2).

X-ray crystallographic analysis

Selected crystallographic experimental details for 1 and 2 are shown in Table S1.† Both complexes crystallise in the monoclinic space group P2₁/n. The asymmetric unit of 1 and 2 contains one [Mn³⁺][μ₂-O]₂(CH₃COO)₄(L₁)₂⁻ anion (1) or [Mn³⁺][μ₂-O]₂(CH₃COO)₄(L₂)₂⁻ anion (2), one HNEt₃⁺ cation, and several solvent molecules (four water and four acetonitrile molecules for 1; one acetonitrile and two methanol molecules for 2). Note that for 2 a poorly defined solvent region was additionally treated using SQUEEZE.₂⁸ The solvent accessible voids were calculated to be 190 Å³ containing 42 electrons per complex which can be attributed to 4 molecules of H₂O, given the results from the elemental analysis. As both anionic complexes are isostructural, the following description is valid for 1 and 2 (see structure in Fig. S1 of the ESI†). The structure of 1 involves five Mn(III) ions arranged within two fused {Mn₃O} units which share a central Mn(III) ion (Fig. 2). The oxidation state of each manganese centre has been confirmed by bond length and charge balance considerations, and also by bond valence sum calculations (BVS) with values presented in Table S2.† The two corner-sharing {Mn₃O} units lie in planes almost perpendicular to one another with angles of 86.84° (1) and 86.75° (2) (see Fig. S2 of the ESI†). Each Mn(III) center displays a tetragonally distorted octahedral geometry through the coordination of four doubly deprotonated Schiff base ligands (L₁²⁻ for 1, and L₂²⁻ for 2) and four bidentate acetate auxiliary ligands (Fig. 2). Two different Mn(III) ions can be distinguished based on the dissimilarities of their first coordination sphere (see Fig. 2 and Fig. S1 of the ESI†). The central Mn₁ shared by the two fused {Mn₃O} units is surrounded by four ligand units (L₁²⁻ for 1, and L₂²⁻ for 2) through the coordination of four N-donor atoms from the triazole rings. Moreover, two μ₂-oxo bridges (O₁, O₂) fill the remaining equatorial positions of Mn₁. These o xo groups also connect the central Mn₁ ion with the outer manganese ions (Mn₂, Mn₃, Mn₄, Mn₅) with average Mn-O bond distances of 1.885(2) Å for 1 and 1.887(5) Å for 2. Each outer Mn(III) ion is further coordinated by one phenolic oxygen and two N atoms, a nitrogen from the triazole ring of one ligand and the iminic nitrogen of another. Two bidentate acetate anions are additionally bound which link each ion to the adjacent peripheral Mn(III) (see Fig. 2). The intramolecular Mn···Mn’ distances can be divided in two groups: those between the central manganese atom Mn₁ and the peripheral ones Mn₂–Mn₅ (d⁴⁻⁻Mn₃–Mn₅ = 3.252(8) Å for 1, and 3.253(1) Å for 2), and those between the outer Mn(III) ions linked by the acetate groups (3.291(7) Å for 1, and 3.300(1) Å for 2).

The outer manganese centres (Mn₂–Mn₅) in 1 and 2 display a characteristic elongated Jahn–Teller (JT) distortion (Fig. 3), as expected for high-spin d⁴ Mn(III) ions (d^⁴⁻⁻Mn₃–Mn₅ = 2.298 Å (1), 2.283 Å (2); d^⁴⁻⁻Mn₃–Mn₅ = 2.033 Å (1), 2.032 Å (2)). The elongated JT axis around the central manganese (Mn₁) however is comparatively less distinct. This is evident considering the bond lengths around Mn₂–Mn₅ as internal standards, and comparing these to those of Mn₁. The Mn₁–N
distances (N1A–Mn1–N1B) are shorter than expected (2.162 Å (1), 2.158 Å (2)) and the Mn1–N distances (N1C–Mn1–N1D) are slightly longer than would be expected (2.096 Å (1), 2.074 Å (2)) compared to those of the outer Mn(ii) ions. This indicates possible disorder of the JT axis between these two positions.18 Note, the Mn1–O1 and Mn–O2 distances are as expected on comparison to the other Mn–O distances not situated along the JT axes of Mn2–Mn5. We have therefore assumed the axis defined by O1–Mn1–O2 is not involved in the disorder.

An extensive search of the Cambridge Structural Database (CSD 5.38, June 2017) reveals the rarity of the metal-oxo assembly above) were considered for complexes 

\[ Mn(III) centres of each peripheral pair (\(J_2\)). The \(g\) parameter was included as a fixed value of \(g = 1.98\,^{45,47}\). The best fit gives the coupling constants \(J_1 = -3.10\ \text{cm}^{-1} (1)\), \(-2.82\ \text{cm}^{-1} (2)\), and \(J_2 = -8.26\ \text{cm}^{-1} (1)\), \(-7.43\ \text{cm}^{-1} (2)\) (\(R = 98\%\) and 95\%). Antiferromagnetic interactions are also seen in a mixed-valence \(\{Mn^{II}\}^{2}\) complex with a related structure \((J_1 = -1.15\ \text{cm}^{-1} and J_2 = -2.40\ \text{cm}^{-1})\).41 Given the magnitude of the exchange interactions it is clear that axial zero-field splitting (\(D\)) should also be included, as this can be of the same order of magnitude as \(J_1\).3 However all attempts to include \(D\) lead to unreasonable values and/or prevent the fits from converging.

\[
\hat{H} = - 2J_1 (\hat{S}_1 \hat{S}_2 + \hat{S}_3 \hat{S}_4) - 2J_2 (\hat{S}_3 \hat{S}_4 + \hat{S}_1 \hat{S}_2) + g\mu_B B \sum_{i=1}^{5} \hat{s}_i
\]

(1)

The simple exchange-coupling model which ignores ZFS suggests that the ground state of both \(1\) and \(2\) is \(S = 0\) with low-lying excited states: the closest lying \(S = 1\) state within \(3\ \text{cm}^{-1}\) and the closest lying \(S = 2\) state within \(6\ \text{cm}^{-1}\) (Fig. S5†). The magnetisation curves (Fig. S6†) would then result from population of these low-lying \(S > 0\) states. Note that inclusion of single-ion ZFS in the model (\textit{vide supra}) could modify the obtained \(J\) values and hence the ordering of the spin states, which may reveal a non-zero ground state. Additional alternating-current (ac) measurements were performed, with the absence of any frequency-dependent out-of-phase signal (Fig. S7†) consistent with either an \(S = 0\) ground state or a small spin ground state with a negligible \(D\) parameter. Note that the Jahn–Teller axes of the four outer manganese ions are nearly perpendicular to each other (Fig. 3), which would yield a relatively small net axial magnetic anisotropy.48

Electrochemical studies

Along with the redox properties of the metal ions, Schiff base ligands can potentially impart intriguing redox activity to their
The redox behavior of complexes 1 and 2 was therefore probed by cyclic voltammetry (CV). Fig. 5a shows the CV of compound 2 over the range +1 to −2.5 V vs. the ferrocene/ferrocenium couple (the CV of complex 1 over the same range is very similar). A CV of ligand H₂L₁ is provided in the ESI (Fig. S8†) for comparison. Fig. 5a indicates that at least two essentially irreversible reductive redox processes that cannot be attributed to the free ligand are evident at around −0.9 V and −1.8 V. These reductive waves did not become more reversible when the scan window was restricted. However, in the oxidative portion of the voltammogram, a more reversible wave (centred around +0.25 V) was apparent. Fig. 5b shows a comparison of the CVs for this oxidative process for complexes 1 and 2 over a narrower potential window than in Fig. 5a. Again, the free ligand shows no redox waves in this region (Fig. S8†). The shape profile was very similar in both cases, and $E_{1/2}$ values of 0.21 V and 0.23 V were obtained for complexes 1 and 2 respectively (these values are the same within the ±20 mV error quoted for the type of Ag/AgNO₃ pseudo reference employed). Taken together, and in view of the structural similarities between complexes 1 and 2, these data suggest that the redox process giving rise to this wave has the same origin in both complexes.

Bulk electrolysis on complex 1 at +0.47 V indicated that the charge passed during this oxidation process was equal to 95% of that expected for a one-electron process. It is therefore plausible that this redox process corresponds to the one-electron oxidation and re-reduction of the unique, central Mn(III) centre Mn1 in these complexes given the different coordination environment displayed − {MnN₄O₂} − compared to Mn₂−5 − {MnN₂O₄}. The kinetics of the redox process giving rise to the wave at +0.21 V for complex 1 were probed by scan-rate dependency studies. As is evident from Fig. 6, the return (cathodic) peak currents are always smaller than the oxidative currents, with this effect becoming less apparent as the scan rate is increased (i.e. the wave becomes more reversible the shorter the length of time the compound remains oxidised). This is consistent with an oxidation process followed by an irreversible chemical decomposition. Thus at fast scan rates, there is a greater chance that the complex can be reduced back to its original form before decomposition can occur. Moreover, Fig. 6 shows that even at slow scan-rates, the peak-to-peak separation is well over 100 mV, indicating that electron transfer is rather slow. This could imply that a structural re-arrangement occurs during this redox event and the associated geometrical changes required around a Mn(III) centre upon oxidation to Mn(IV) (and upon re-reduction to Mn(III)) could account for the slow electron transfer observed. It is interesting to note that the crystallographic analysis indicates possible disorder of the Jahn–Teller axis at the central Mn(III), which may make the redox event easier at this site.

### Conclusions

We have shown for the first time that the 1,2,4-triazole derivatives H₂L₁ and H₂L₂ can be utilised in the synthesis of polynuclear transition complexes. This leads to two novel penta-nuclear Mn(III)-based complexes with an unusual twisted bow-tie structure, where the Mn(III) ions are antiferromagnetically coupled. The electrochemical studies reveal a quasi-reversible redox process: a one-electron oxidation Mn(III) → Mn(IV) and re-reduction Mn(IV) → Mn(III) which we suggest to be centred at the central Mn(III) ion in both complexes. Future work will focus on modifying the Schiff base ligands to impart...
additional redox states towards redox-switchable molecular magnetic materials.
